Scholarships.—Scholarships and prizes are open to competition: T. 112 guineas each, awarded after a anatomy and physio-logy; Radcliffe 112 guineas each, awarded after a dermatalogy for one year, value about £200; a scholarship in pathology of a sum not exceeding £400 per annum; Leslie Pearce Gould Research Scholarship in surgery for one year, value about £200; the Atkinson Morley Scholarship of £45 a year for three years, awarded after examination in the theory and practice of surgery; the Atchison Scholarship of £55 a year for two years for general proficiency in medical studies; the Magrath Clinical Scholarship, value about £100; the Filitier Exhibition in pathology of £30; the Percival Alkaya Prize for the advancement of surgery by research, value about £60; the Graham Gold Medal for research work; four Fellows Medals in clinical medicine; Liston Medals in clinical surgery; the Bruce Medal in pathology and surgery; two Tuke Medals in pathology; and the Erichsen Prize for practical surgery.

Fees.—The fee for the full course of final studies at the school is 112 guineas if paid in one sum, or 115 guineas if paid in two instalments. Fees for vaccination and fevers not included.

Appointment.—The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, surgical registrar, obstetric registrar, casualty medical officers, casualty surgical officers, assistants in ear, nose and throat, ophthalmic, skin and venereal diseases departments, and house anaesthetists.

Particulars of general and special courses can be obtained on application to the Dean of the Medical School, University College Hospital, University Street, W.C.1.

WESTMINSTER HOSPITAL.

This school, with its hospital, situate in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College. The rest of the work is done in the school buildings near the hospital. The number of in-patients averages 3,000 and out-patients upwards of 30,000 annually, and the hospital and school afford ample facilities for instruction in all branches of medicine and surgery.

Appointments.—A medical, surgical, and obstetric registrar are appointed annually, each with a salary of £50. Two house-physicians, three house-surgeons, one assistant house-physician, one assistant house-surgeon, and a resident obstetric assistant are appointed after examination, and are provided with rooms, commons, and salary of £50 per annum, except the assistant house-physician and the assistant house-surgeon, who are provided with commons only. The assistant house-physician after three months' service becomes house-physician for a further period of six months, and the assistant house-surgeon after three months' service becomes house-surgeon for a further period of six months. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among qualified students. Every student must perform the duties of out-patient dresser for four months, and afterwards hold the office of in-patient dresser for four months. He is also required to serve two terms of four months each as medical clinical clerk to in-patient physician and one term as gynaecological clinical clerk. Two pathological clerks are appointed every four months to assist in the post mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

Scholarships.—The following scholarships are offered for competition during the year 1922-23: In the summer session two natural science scholarships, £60 and £30, and one in Arts, £60. In the winter session two scholarships in anatomy and physiology, £50 each. In the spring two scholarships in anatomy and physiology, £50 each.

Fees.—The annual composition fee is 35 guineas. An entrance fee of 10 guineas is payable by all students—namely, primary and intermediate students, £10 10s.; students entering for the final subjects, £8 8s. These fees include subscriptions for membership of the Clubs Union.

Further information and a prospectus can be obtained on application to the Dean at the Westminster Hospital, Westminster, S.W.1.

The Governors of the Hospital propose in the near future to carry out extensive improvements and alterations to the Hospital which will render it a still more efficient teaching institution.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

The school is situated at 8, Hunter Street, Brunswick Square, W.C.1, close to the Royal Free Hospital. An agreement has also been made under which a certain number of students of the school can receive clinical instruction at St. Mary's Hospital, Paddington. It is, like all the other London schools which have so far been mentioned, one of the constituent schools of London University. The school buildings have recently been enlarged. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of the University of London. Research laboratories are attached to all departments. A large, well-equipped library, common room, Union room, and refectory are provided for the use of students. Resident accommodation

for 50 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 240 beds, all of which are available for clinical instruction. A new block contains the Obstetrical and Gynaecological Unit, which, with the Marlborough Maternity Department, controls 68 beds. There are separate departments for diseases of the eye, ear, and skin, massage, electrical and x-ray work, dentistry, and casualty. The instruction given covers the full curriculum for the M.B., B.S. degrees of the University of London. Students attending at St. Mary's Hospital (305 beds) are admitted to the full clinical course and educational facilities of that hospital. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board and receive special instruction in lunacy at Bethlem Hospital; they are also admitted to the practice of a number of special hospitals.

Arrangements are made for students to hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, Hospital for Sick Children, the National Hospital for Nervous Diseases, and the South London Hospital. The work of the school includes preparation for the Primary Fellowship examination, and also for the medical school and general hospital course for dental students.

Appointments.—Qualified students of the school can obtain appointments as house-physicians and house surgeons, obstetric assistants, surgical, gynaecological, and medical registrars, assistant pathologists, assistant anaesthetists, medical electrician, skiagrapher, and clinical assistants and demonstrators in various subjects.

Scholarships.—The Isabel Thorne Entrance Scholarship value £30, the St. Dunstan's Medical Exhibition value £60 a year for three years, which may be extended to five years, and the Mabel Sharnan-Crawford Scholarship value £20 a year for four years, are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship of the value of £75 a year for four years, the Mrs. George M. Smith Scholarship of the value of £50 a year for three years, which may be extended to five years, the Dr. Margaret Todd Scholarship of the value of £37 10s. a year for four years, and the Saml Holborn Scholarship of the value of £25 a year for three years, which may be extended to five years, are awarded in alternate years. The Bostock Scholarship, value £60 a year for two or four years, is awarded by the Reid Trustees on the result of an examination held in May by the University of London every fourth year. The holder of the scholarship must enter the London School of Medicine for Women. The Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, of the value of £25 a year for four years, is awarded every fourth year. The Ellen Walker Bursary of £25 for two years is awarded each year to a student beginning her fourth year of study. The John Byron Bursary of £20 a year for two years, the Helen Pridoux Prize of £40, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Butler Scholarship of £14 10s. a year for four years, together with many other scholarships and prizes, are offered on sundry conditions. The Dr. Edith Pechey-Philpott Post-Graduate Scholarship of £100 is awarded annually. Various missionary societies also offer scholarships on certain conditions, and assist ladies who wish to go to India and other countries as medical missionaries.

Fees.—Courses for the University of London degrees and the diplomas of the Conjoint Board in England, and other qualifications: First medical examination, £35, course for second and third, £205; course after the second medical examination, £115. These sums include library and laboratory fees.

The Students' Union exists to promote corporate action of the students on matters of common interest, and to promote and maintain athletic and other clubs. All students are required to become members of the Union.

Further information can be obtained from the Warden and Secretary.

KING'S COLLEGE.

Since the incorporation of King's College in the University of London the instruction given to medical students is carried out there in the classes of the Faculty of Science (Medical Division), and deals only with the subjects of the preliminary and intermediate parts of the curriculum. King's College Hospital (see p. 427) is now a separate institution, and the studies for the final examinations only are carried out there. A special class for the Matriculation Examination is also held.

There is a large athletic ground at Mitcham, managed by the Students' Union Society.

Scholarships.—The entrance Scholarships are: 1. Two Warneford Scholarships, each £30 for four years; subjects—selected from mathematics, classics, divinity, and science. 2. One Sambrook Exhibition of £25 for two years, open; subjects of examination—mathematics, elementary physics, inorganic chemistry, botany, zoology, and geology. The holders of the preceding awards must proceed to King's College Hospital. 3. Worsley, £100, paid in five

ual instalments. 4. Rabbeth Scholarship, value £20, in July, the best student of the first year. 5. Second year's scholarship, value £20, for the best student of the second year. 6. Daniell Scholarship, £40, awarded on the results of the University Honours examination.

Women Students.—King's College is now open to women students for the Preliminary and Intermediate portions of the medical curriculum. Applications for admission should be made to the Dean.

Information as to fees can be obtained from the Dean of the Medical Faculty at the College, Strand, W.C.2.

Information as to scholarships and subjects of examination can be obtained from the Secretary of the College.

UNIVERSITY COLLEGE.

Its institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in a group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy, physiology, and pharmacology. The Department of Hygiene and Public Health prepares for the diplomas of public health of the Royal Colleges and of the various universities. Research work is undertaken in all the above-mentioned departments. The College undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the cognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students may join the College for any of them. Women students are admitted to all courses on the same terms as men. The moral arrangements for the benefit of students include membership of the Union Society or the Women's Union Society with the College gymnasium and the athletic grounds. There is also a collegiate residence for about fifty-five men students at Ealing, and for about seventy women students at yng Place, Gordon Square.

Scholarships.—The scholarships and exhibitions obtainable include the Bucknill Scholarship, value 135 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School), and entrance exhibitions in the same subjects, each of the value of 5 guineas.

Fees.—The fees for the courses covering the work of the First Examination for medical degrees of the University of London, and for both parts of the Second Examination, amount to 115 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England also amount to 115 guineas. These fees may be divided into payments for the different courses which it may be desired to take out, but do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Secretary of University College, Tower Street, London, W.C.1.

THE PROVINCES.

There are in England and Wales, not counting London, over 100 medical schools, each, with one exception, supplying instruction in the full medical curriculum. Accounts of them are given in the following. In several cases there is appended information concerning hospitals other than those directly connected with the school in question; such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

OXFORD AND CAMBRIDGE.

Both at Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently furnished, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them, but this is not commonly done. The local hospitals, though well equipped, are comparatively small. The university authorities therefore encourage the students, as soon as they have completed the earlier examina-

tions and taken a degree in Arts, to join some London school, and thus spend the time of their preparation for the final examinations in a city where the opportunities for gaining clinical knowledge are greater and more varied. A considerable proportion of Oxford and Cambridge medical students take the London Conjoint diplomas before graduating in medicine and surgery at their own university.

BIRMINGHAM.

The school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, classrooms, and other necessities devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for this purpose. Together they have upwards of 600 beds for medical, surgical, and special cases, and with an array of special departments of all kinds, including one for lying-in women. Clinical instruction is given in the wards and out-patient and special departments daily, and formal clinical lectures delivered weekly throughout the winter and summer sessions. Special tutorial classes are also held alike for the degrees of Birmingham and some other universities and for the diplomas of corporations.

Appointments.—The large number of appointments open to past or other students includes the following:—At the General Hospital: surgical registrar, £200 a year; one resident medical officer, salary £155 a year; one resident surgical officer, salary £180 a year; one resident pathologist, salary £100 a year; two visiting anaesthetists, salary £50 a year; four house-surgeons, office tenable for nine months, £100 a year; one house-surgeon to the gynaecological and one to the special departments, each tenable for six months, £100 a year; three house-physicians, post tenable for six months, £100 a year. At the Queen's Hospital: three house-physicians and three house-surgeons (posts vacant in January and April); one obstetric and one ophthalmic house-surgeon (posts vacant in April and October). These appointments are tenable for six months. Salaries at the rate of £90 per annum, with board, lodging, and washing. One resident dresser, tenable for three months; candidates must previously have attended their third year lectures, etc., and need not be qualified; honorarium, £13 13s. on completion of duties. Four non-resident obstetric students who hold office for one month and receive board only at a payment of £1 1s. a week. At the Maternity Hospital: one house-surgeon, salary £50 a year. At the City Workhouse and Workhouse Infirmary: five resident medical officers. At the Birmingham General and Branch Dispensaries: twelve resident surgeons. At the Birmingham Mental Hospitals: five assistant medical officers. At the City Fever Hospitals: three assistant medical officers. At the Children's Hospital: one resident surgical officer, one resident medical officer. At the Birmingham and Midland Eye Hospital: four resident surgeons. At the Orthopaedic and Spinal Hospital: two clinical assistants (non-resident). At the Ear and Throat Hospital: one house-surgeon, £70 a year; four clinical assistants (non-resident). Four non-resident Poor Law appointments are in the gift of the Board of Guardians.

Scholarships.—There are numerous money and other awards for students of sufficient merit, among them being the following: The Walter Myers Travelling Studentship of £300, offered in 1922, and in each alternate year succeeding, tenable for one year; the Sands-Cox Scholarship of £42 (an extra Faculty of Medicine, awarded on either M.B. marks); four Queen's Scholarships of £10 10s. each, awarded annually at the second, third, fourth, and final university examinations respectively; one or more Sydenham Scholarships, allotted on entrance to students who are the sons of deceased medical men; the English Scholarship of £10 for proficiency in midwifery and the English Scholarship of £10 for proficiency in surgery; the Foxwell Memorial Gold Medal and Silver Medal, awarded on the final examination. There is also an entrance scholarship of £31 10s. for students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded annually as follows: Senior Medical prize, Gold Medal; Senior Surgical Prize, Gold Medal; Midwifery Prize, Gold Medal; Junior Medical Prize, Silver Medal; Junior Surgical Prize, Silver Medal.

Fees.—The composition fee for university classes is £105 5s. This covers all the work required for the degrees of Birmingham and some other universities, and for the ordinary qualifications of licensing corporations, but not the additional courses required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State Medicine, and some other special work. The total cost for the five years' curriculum, including hospital and examination fees, is estimated at £197 0s. 6d.

Other information should be sought from the Dean of the Medical Faculty, University, Edmund Street, Birmingham.

BRISTOL.

THE school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and diplomas. The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them about 600 beds and extensive out-patient departments, special clinics for diseases of women and children, and those of the eye, throat, and ear, in addition to arrangements for dental work and large outdoor maternity departments. At each of these institutions there are well-arranged pathological departments, comprising large pathological museums, *post-mortem* rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for x-ray work both in diagnosis and treatment, the various forms of electrical treatment, including high-frequency currents, electric baths, Finzen light treatment, and massage.

The students of the school have also the advantage of attending the practice of the Royal Hospital for Sick Children and Women, containing 108 beds, and that of the Bristol Eye Hospital, with 40 beds. Excellent facilities are thus afforded to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work. Each student has the opportunity of personally studying a large number of cases and acquiring practical skill in diagnosis and treatment. All classes are open to women.

Appointments.—(1) Undergraduate: Clinical clerkships, dresserships, also ophthalmic, obstetric, and pathological clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate—At the Bristol Royal Infirmary: Four house-surgeons, £120 each per annum; two house-physicians, £120; resident obstetric and ophthalmic house-surgeon, £120; throat, nose and ear house-surgeon, £120; dental house-surgeon, £120. All these appointments are made for twelve months. From the resident officers a senior resident officer is appointed at a salary of £200. At the Bristol General Hospital: Senior resident medical officer, £300 per annum; casualty house-surgeon, £175 per annum; two house-physicians, £175 per annum; house-surgeon, £175 per annum; obstetric house-surgeon, £175 per annum; dental house-surgeon, £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years.

Scholarships.—The following are among the scholarships and other awards open to students of the school: Two Martin Memorial Pathological Scholarships of £10 each; the Tibbitts Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value 7 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in surgery; the Leonard Prize, value 7 guineas, for a gold medal; the Medical Prize, a gold medal and 7 guineas, for proficiency in surgery; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose and throat, value £14.

Fees.—The fee for all the courses required for the medical curriculum, including hospital practice, is 205 guineas, paid by annual instalments.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.

The Welsh National School of Medicine.

STUDENTS can complete the whole of their curriculum in the school. The courses of instruction are fully adapted to meet the needs of those students studying for the degrees in Medicine and Surgery of the University of Wales, and also for the degrees of other universities and for the diplomas of licensing bodies. All classes are open to both men and women students.

Medical men wishing to prepare for the Diploma in Public Health or the Tuberculous Diseases Diploma of the University of Wales can attend complete courses of instruction in the school.

Prospectuses can be obtained on application to the Dean of the Faculty of Medicine, or to Mr. D. J. A. Brown, Secretary, at University College, Cardiff.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

Thus, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, Newcastle-on-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the

latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College, also part of the university, and their clinical work in the Royal Victoria Infirmary, an institution with over 600 beds and special accommodation for the benefit of students. In a health wing of the school itself there are the departments of bacteriology and physiology. There are also in this wing a gymnasium and a set of rooms for the use of the Students' Union.

Appointments.—Assistant demonstrators of anatomy and prosecutors for the professor of anatomy, assistant physiologists, pathological assistants, assistants to the dental surgeon, and assistants in the eye department, throat and ear department, and department for skin diseases, are elected annually. Clinical clerks and dressers are appointed every three months.

Scholarships.—A University of Durham Scholarship, value £25 a year for four years, for proficiency in arts, open annually at the beginning of the winter session to intending students. The Pears Scholarship, value £150, for proficiency in arts (when vacant). The Dickinson Memorial Scholarship, interest of £400, with a gold medal for medicine, surgery, midwifery, and pathology, open to perpetual students in their fifth year. The Tulloch Scholarship, interest of £400 annually, for elementary anatomy, biology, chemistry, and physics, for students at the end of their first year. The Charlton Memorial Scholarship, interest of £700 annually, open to full students entered for the class of medicine, at the end of their fourth or fifth winter. The Gibb Scholarship, interest of £500 annually, for pathology, at the end of summer session. Gibson Prize, interest of £250 stock, for midwifery. Outerson Wood Prize, interest of £250, for psychological medicine. The Goyder Memorial Scholarship, proceeds of £325; subjects: clinical medicine and clinical surgery. Luke Armstrong Memorial Scholarship, proceeds of £680, for best essay in some subject in comparative pathology. The Stephen Scott Scholarship in Surgery, interest on £1,000 annually. The Heath Scholarship in Surgery, of the value of £200, awarded every other year. First award in 1896. Philipson Scholarships (2), the interest on £1,800, to the candidates who obtain the highest marks in the Final M.B., B.S. examinations held in March and June respectively.

Fees.—The composition fee for lectures at the college is £122. Composition fee for hospital practice, £46, plus £2 2s. yearly for three years, payable to the Committee of the Royal Victoria Infirmary. Other information should be sought from the Registrar of the College of Medicine at Newcastle.

LEEDS.

THE School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1894, and contain excellent dissecting rooms, several well-arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar classrooms. In addition, there are a library and reading room and two museums, one being devoted to pathology and the other to anatomy. The comfort of the students is secured by common rooms and a refectory in which they can take meals. The General Infirmary has 620 beds, and includes gynaecological and ophthalmic wards and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the Infirmary, have 88 beds. The West Riding Lunatic Asylum at Wakefield is also open for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary (where the practical instruction in dental subjects is also given), the City Fever Hospitals (800 beds), the Hospital for Women and Children, and the Leeds Maternity Hospital.

Appointments.—One senior anaesthetist, £50; seven anaesthetists, £25 each; a medical and a surgical tutor, at £125 each per annum; one resident medical and one resident surgical officer, each at £150 per annum; one casualty officer, at £125 per annum; one resident ophthalmic officer, at £100 per annum; one resident aural officer, at £100 per annum; one resident obstetric officer, at £50 (attached to the gynaecological ward); one ophthalmic house-surgeon, at £50 per annum; three house-physicians, each holding office for six months, and four house-surgeons, holding office for six or twelve months. Surgical dressers are appointed every six months; physicians' clerks, ophthalmic and aural dressers, gynaecological ward clerks, gynaecological out-patient clerks, maternity clerks, assistant physicians' clerk, dermatological clerks and assistant surgeons' dressers, dressers in the

¹ New arrangements are being made from October next.

sanitary room, post-mortem clerks, and laboratory assistants every three months, and dressers in the venereal clinic every month. A resident medical officer (honorarium at rate of £60 per annum) is also appointed every six months for the Ida semi-convalescent Hospital. Appointments are also open to students at the Leeds Public Dispensary (four resident medical officers, with salaries commencing at £80), at the hospital for Women (two house-surgeons, at £50 per annum, and two anaesthetists, £20), and at the West Riding Asylums.

Scholarships.—The university awards annually a scholarship in the form of a free admission to the lectures and classes given in the university, which are covered by the composition fee. The university also awards a scholarship on the results of the first examination, of the value of £88, in the form of a free admission to the clinical teaching of the infirmary.

Fees.—It is estimated by the authorities that the approximate cost of medical education to a student in this university is £300, but, of course, the expenses of living during the five years covered by the curriculum. The fee for a complete course for the First M.B. is £41; the composition fee for the course for the second and third examinations, and for the clinical work at the infirmary, is £74. The composition and clinical fee for those who have passed the second examination is £130.

Further information can be obtained from the Dean and Clinical Sub-dean, School of Medicine, Leeds.

LIVERPOOL.

The Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well-equipped classrooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratory and other rooms are situated close to one another and intercommunicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals, of which an account is given below, have amalgamated to form the clinical school of the university.

Appointments.—The nature of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming its clinical department.

Scholarships.—The awards made each year to successful students total over £1,500. They include the following: Two Holt Fellowships, one in Pathology, the other in Physiology; a Robert Gee Fellowship in Anatomy; two John Rankin Fellowships in Anatomy; a John W. Bacteriology; a Johnston Colver Fellowship in G. n Ethel Boyce as Fellowship in Surgical Pathology; one University Fellowship (value of Fellowships: one at £150, two at £120, seven at £100); a University Scholarship of £25, awarded on the results of the Second M.B. Examinations; a Scholarship in Mechanical Dentistry of £20; two Lyon Jones Scholarships, of the annual value of £21 each for two years, one for the junior and the other for senior students; the Derby Exhibition of £15; the Clinical School Exhibition of £15; the Owen T. Williams Prize; the Torr Gold Medal in Anatomy; John Rankin Exhibition in Practical Anatomy, £25; the George Holt Medal in Physiology; the Kankath Medal in Pathology; Mitchell Banks Medal in Anatomy; the Robert Gee Prize of £5 5s. in Children's Diseases; Mary Birrell Davies Memorial Scholarship, £60 per annum for four years; two Robert Gee Entrance Scholarships, each of the value of £25 per annum for two years; Dental Operating Prizes (four); Orthodontia Prizes (two); Samuels Memorial Scholarships, three at £20 each; one Thomas H. Bickerton Prize in Anatomy; Dr. N. E. Robert Prize in Zymotic Diseases; Ash's Prize in Dental Surgery, value £2 2s.; Gilmore Medal; and other Entrance Scholarships.

Fees.—Information as to the fees for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

The Clinical School.

As many as nine hospitals have combined to form the clinical school of the university, these being: The Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, the Royal Liverpool Children's Hospital, the Hospital for Women, the Eye and Ear Infirmary, St. Paul's Eye Hospital, and St. George's Hospital for Diseases of the Skin. Between them they provide about 1,140 beds.

MANCHESTER.

The staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature. The work of the undergraduates is done chiefly in con-

nexion with the Royal Infirmary, an institution which itself contains about 670 beds, and has associated with it a large convalescent home (136 beds), and the Royal Lunatic Asylum at Cheadle (430 beds). Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

Appointments.—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: A surgical registrar, at £150 per annum; a pathological registrar, at £350 per annum; two medical registrars, at £150 per annum; a surgical tutor, at £30 per annum; a director of the clinical laboratory, at £400 per annum, and one assistant director at £300; three assistant medical officers and three assistant surgical officers, each at £35 per annum; one assistant surgical officer, antral department, at £35 per annum; five anaesthetists, two at £75 and three at £100 per annum; one radiological registrar, at £250 per annum; one resident medical officer, one year, £250 per annum; ditto at Cheadle, one year, £300 per annum; one resident surgical officer, one year, £250 per annum; two resident medical officers for Central Branch, £200 and £100 per annum; one accident room house-surgeon, six months, £200 per annum; one assistant medical officer at the Convalescent Hospital at Cheadle, appointed every six months, at a salary of £80 per annum; ten senior and ten junior house-surgeons and ten house-physicians, appointed during the year for a term of six months, at a salary of £50 for the first six months, and £100 for the second six months. Resident officers are appointed to the gynaecological, the eye, and the ear and throat departments every three months. Clinical clerks and surgical dressers are appointed to the various departments of the hospital every three months.

Entrance and other Scholarships.—The following are among the scholarships obtainable by students of the school: Rogers and Seaton Scholarships in Arts (in alternate years), £40 per annum, tenable for two years. Derby Entrance Scholarship in Mathematics, tenable for one year, value £25, one being awarded annually, except in such years as a Cartwright Scholarship is awarded. Cartwright Scholarship, £35 per annum, tenable for three years. Three Hulme Scholarships, tenable for three years, of £35, one being awarded annually for proficiency in subjects of general education. Two James Gaskill Scholarships of £35, tenable for two years, one being awarded annually for proficiency in the branches of Mechanics and Chemistry. A Dora Muir Scholarship, £30 per annum, tenable for three years, and open to the competition of women students only. This is awarded triennially. Sir J. P. Kay-Shuttleworth Scholarship, £30 per annum, tenable for three years, awarded triennially, open to the competition of scholars from Sedburgh School, Giggleswick School, and Burnley Grammar School. Subjects: Mathematics, Chemistry, and Mechanics. Dreschfeld Memorial Scholarship, value £20, tenable triennially on the result of the Entrance Modern Languages Examination, £20, and the University Medical Scholarships, value £20 per year, for candidates who have not commenced the second year of study leading to a medical qualification.

Subjects: Zoology, Botany, and Chemistry. Two Entrance Scholarships in Medicine, value 160 guineas, awarded annually for proficiency in Arts or Science respectively. One Research Fellowship in Public Health of £100, awarded annually. Tom Jones Exhibition in Anatomy, £25, offered annually. A Robert Platt Physiological Scholarship of £90, tenable for one year. A Leech Fellowship of £100 for original research after graduation. A Graduate Scholarship in Medicine, value £25, tenable for one year, awarded annually for proficiency shown at Final M.B. Examination. A Dunville Surgical Prize, value £15, awarded annually at graduation. The Tom Jones Memorial Surgical Scholarship, value £50, tenable for one year, awarded usually annually. The Turner Medical Prize, value £20, awarded annually for proficiency in certain subjects of the Final M.B., Ch.B. Examination. The John Henry Agnew Scholarship of £30, awarded annually for proficiency in the Diseases of Children. The Ashby Memorial Scholarship, tenable for one year (£100), for research in the Diseases of Children; offered triennially. Sidney Redshaw Exhibition in Physiology: one offered annually. The details and regulations of the Dickinson Scholarships—(1) for Anatomy, (2) for Pathology, (3) Research Scholarship in Surgery, and (4) Travelling Scholarship in Medicine—may be obtained from the Secretary to the Trustees. The Sam Gamble Scholarships—the trustees are prepared to award four scholarships of not less than £40 per annum, tenable for not more than four years, to women students who have passed the first M.B. Examination; the conditions can be obtained from the Registrar. The Knight Prize of £50 for original research in the psychological factors in the causation of mental disorder—open to holders of the Diploma in Psychological Medicine or medical practitioners who have been registered in the university as candidates for that diploma.

Fees.—The composition fee for the university course in medicine is 104 guineas, payable in four instalments of 26 guineas, but this sum does not include the fee to cover the work required for the first M.B. Examination. This is 35 guineas, payable in one sum. Hospital fees are additional and usually amount to about 77 guineas.

A prospectus and further information about the school and scholarships may be obtained from the Registrar.

Clinical Work.—The Royal Eye Hospital, the Hospital for Diseases of the Skin, the Manchester Northern Hospital for Women and Children, the well-known Hospitals for Children at Pendlebury, and St. Mary's Hospital for Diseases of Women and Children, all make arrangements for the instruction of students.

SHEFFIELD.

In this city the Medical School is one of the departments of the University, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangement and scientific equipment, on the most modern and complete lines.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum which is open daily. In addition, there is a museum devoted to materia medica specimens, and a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms both for men and women students. In the university buildings there is a refectory open to all students of the school, and a university journal is published each term. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 500 beds for medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them; whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the *post-mortem* examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students are able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for Sick Children, while special courses on fever are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Asylum.

Appointments.—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) Casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. These appointments are made for three months, commencing on the first day of October, January, April, and July.

Scholarships.—Entrance Medical Scholarship, value about £180, open to both sexes. Four Edgar Allen Scholarships of £125 a year for three years may be held by students taking the degree course in Medicine. Two Town Trustees' Scholarships, each of the value of £50, tenable for three years, for boys or girls under the age of 19 years who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination. Four Town Trustees' Scholarships, value £50, for boys or girls under 19 years of age, educated in any school in Sheffield, secondary or otherwise. Town Trustees' Fellowship, value £75, tenable for one year. Mechanics' Institute Fellowship, value £50 (with remission of fees), tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50, tenable for two years. Kave Scholarship, for proficiency in anatomy and physiology, value £22 10s. Gold and bronze medals are also awarded for proficiency in various subjects.

Fees.—Students in the Faculty taking their complete course in the university pay an inclusive composition fee of £38 for each of the five years. The fees for special courses taken separately can be ascertained by inquiry of the Dean.

SCOTLAND.

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of the different

Scottish medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified or offer valuable opportunities for post-graduation work.

ABERDEEN.

The school is conducted by the Faculty of Medicine. This comprises twelve chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics, chemistry, anatomy, physiology, materia medica, pathology, forensic medicine, surgery, medicine, and midwifery. Courses of instruction in public health and in tropical medicine are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary (accommodating 270 patients), the Royal Lunatic Asylum (900 patients), the Sick Children's Hospital (85 patients), the City Fever Hospital (250 patients), the General Dispensary, Maternity, and Vaccine Institution (10,000 out-patients annually), and the Ophthalmic Institution (3,000 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital; in fevers at the City Fever Hospital; in insanity at the Royal Asylum; in diseases of ear, nose, and throat at the Infirmary and Dispensary; in diseases of the eye at the Infirmary and Eye Institution; in venereal diseases and diseases of the skin at the Royal Infirmary.

The degrees granted in medicine are: Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Surgery and Bachelor of Medicine (M.B., Ch.B.). A Diploma in Public Health is conferred after examination on graduates in medicine in any university of the United Kingdom.

Bursaries, Scholarships, and Fellowships, to the number of fifty and of the annual value of £1,180, may be held by students of medicine in this university. They range from £8 to £100 per annum, and are tenable in most cases for two or three years. The winter session begins on October 11th, 1922; the summer session on April 23rd, 1923.

Fees.—An inclusive fee of 126 guineas is payable for instruction within the university, and the fee for the degrees of M.B., Ch.B. is 33 guineas. The total cost, including hospital fees, class and matriculation fees, and degree fees, is about £247.

EDINBURGH.

There are three Schools of Medicine: the School of the University, the School of Medicine of the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Edinburgh School of Medicine for Women.

THE UNIVERSITY SCHOOL.—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium, and Museum; Zoological Laboratory and Museum of Science and Art; Physical Laboratory; Chemical Laboratories; Dissecting Room, Bone Room, and Anatomical Museum; Physiological Laboratory; Medical Jurisprudence Laboratories; John Usher Institute of Public Health; Materia Medica Museum and Laboratory; *Post-mortem* Department of the Royal Infirmary and University Pathological and Bacteriological Laboratory; Tutorial Classes of Practice of Physics, of Clinical Medicine, and Clinical Surgery, Surgery, and Midwifery; and the practice of certain other hospitals.

Fees.—The sessional fee for chemistry, anatomy lectures, physiology, midwifery, and public health, is £5. Practical zoology, practical anatomy (summer), morbid anatomy, practical materia medica, mental diseases, practical pathology, and medical entomology and parasitology, £4 4s. Experimental physiology, diseases of tropical climates, practical botany, histology, operative surgery, clinical surgery (per term), experimental pharmacology, and invertebrate zoology, £3 3s. Practical anatomy (winter), £6 16s. 6d. Clinical medicine, £3 13s. 6d. first term, subsequent terms £3 3s. Practical chemistry, £4 14s. 6d. Regional anatomy, chemical physiology, surgical pathology, and applied anatomy, £1 11s. 6d. Tuberculosis, diseases of children, diseases of the eye, diseases of the larynx, ear, and nose, diseases of the skin, and venereal diseases, £2 12s. 6d. Advanced bacteriology, £7 17s. 6d. Clinical gynaecology, £2 2s. Infectious diseases, £1 1s.

Scholarships.—There are many funds for the assistance of students by means of bursaries, scholarships, and prizes, and also awards from the bursary fund for students who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards, and the conditions attaching

QUEEN MARGARET COLLEGE.—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings, with classrooms

reading room, library, etc. They are taught in some classes apart from male students, in others together with them, but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, where wards containing 520 beds are available for their use, and in its dispensary; and similarly in the Western Infirmary and in the Victoria Infirmary; also in the Royal Hospital for Sick Children, the Glasgow Ear Hospital, the Royal Asylum, Gartnavel, Hawkhead Asylum; the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidere and Ruthill; and the Glasgow Royal Maternity and Women's Hospital.

Scholarship.—The Arthur Scholarship, annual value £20, tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October, 1922. This scholarship is restricted to women medical students.

Full information can be obtained from the Mistress, Queen Margaret Hospital.

Board for Students.—A house of residence for women students, Queen Margaret Hall, is situated near the college, in Bute Gardens. The cost of board and residence is from 27s. to 32s. 6d. a week, according to accommodation. Application to be made to the Lady Superintendent. Another hostel near the college is South Park House, Ann Street, belonging to the Student Christian Movement, and open to women students of all colleges in Glasgow. Cost of board is from 28s. to 30s. weekly. Applications to be made to the Warden.

St. Mungo's College.—This is the Medical School of the Royal Infirmary, which is the largest general hospital in Glasgow. The infirmary is situated in Cathedral Square, Castle Street, and has car communication with every part of the city. St. Mungo's College is in the infirmary grounds, and affords full courses in all the subjects of the medical curriculum, and in all the medical subjects of the dental curriculum.

The infirmary has (including the ophthalmic department) over 700 beds; the average number occupied in 1920 being over 600. There are special beds and wards for diseases of women, of the throat, nose and ear, venereal diseases, burns, and septic cases. In the out-patient department the attendances in 1921 numbered 168,610. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat, and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, with the latest and most approved apparatus for diagnosis and treatment.

Appointments.—Five house-physicians and eleven house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees.—The average class fee is £3 3s. for summer classes and £4 4s. for winter classes. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £80. The classes are open to male and female students.

A syllabus of classes can be obtained on application to the Secretary to the Medical Faculty, St. Mungo's College, 86, Castle Street.

THE ANDERSON COLLEGE OF MEDICINE.—This school provides education in all subjects of the curriculum both for medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the University and Western Infirmary. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary; pathology in the Western or Royal Infirmary; vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions stated in the school Calendar). The courses (lectures and laboratory) in "public health" are recognized by the Scottish Licensing Board, the Universities of Oxford, Cambridge, and London, and the London and Irish Colleges.

Fees.—The fees for the lectures and practical work required by ordinary students range between 2 and 5 guineas a session. In the Public Health Department the fee for a six months' course is

£14 14s. The Carnegie Trust pays the fees of students at Anderson College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a postcard by Secretary to the Medical Faculty, the Anderson College Medicine, Glasgow, W., who will forward any further information which may be desired.

The Royal Samaritan Hospital for Women, with over beds, offers facilities for clinical instruction in the discipline peculiar to women. Particulars may be obtained from the honorary secretary, 149, St. Vincent Street, Glasgow.

ST. ANDREWS AND DUNDEE.

The medical departments in these two teaching centres cater specially for students proceeding to the degrees of the University of St. Andrews, but admit other students as well. In the former city the United College provides education in all subjects of the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain fully equipped laboratories. The clinical work of the school is facilitated by various institutions. The class fees are from £6 6s. to £5 12s. 6d. for systematic classes and from £4 14s. 6d. to £4 4s. for practical classes. The hospital ticket is £1 8s. for three months, £4 4s. a year, or perpetual £13 6s. 8d. in one sum. The inclusive or composition fee for the curriculum is £182. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St. Andrews. Information regarding the clinical facilities may be obtained from the Dean of the Medical Faculty, Medical School, Dundee.

Clinical Work.

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given there being recognized for purposes of graduation by all the Scottish Universities, the University of London, the University of Cambridge, the National University of Ireland, and by the Royal Colleges of England and Scotland.

IRELAND.

There is a choice of six schools for those pursuing their medical studies in Ireland. For clinical instruction the choice is equally satisfactory and varied, though the hospitals themselves are comparatively small. Some account of the schools follows.

DUBLIN.

School of Physic.

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians in Ireland, the King's professors of institutes of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dunn's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board of Trinity College. The courses of instruction are open to all medical students whether they belong to the university or not.

The Schools of Surgery.

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the College's own school, combined with two famous old medical schools—Carmichael and Ledwich; they are attached to the College by charter. The buildings contain spacious dissecting rooms, special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the College.

Prizes.—Among the prizes annually awarded are: The Barker Anatomical Prize (£26 5s.); the Carmichael Scholarship (£15); the Mayne Scholarship (£8); the Gold Medal in Surgery, the Stoney Memorial Gold Medal in Anatomy, the H. Macnaughton Jones Gold Medal for Midwifery and Gynaecology; class prizes, accompanied by silver medals, will also be given in each subject.

A prospectus can be obtained post free on application to the Registrar, Royal College of Surgeons, Dublin.

University College, Dublin.

This is one of the constituent colleges of the National University of Ireland, and at present conducts its work at buildings on St. Stephen's Green. It possesses a good library, and the arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. Applications for information may be addressed to the Secretary and Bursar, University College, Dublin.

Clinical Work.

There are numerous well-arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by like bodies elsewhere in the British Isles. Among them are the Mater Misericordiae Hospital, with 345 beds; Dr. Steevens's Hospital at Kingsbridge, with 200; Meath Hospital and County Dublin Infirmary, with 160; Mercer's Hospital, close to Trinity College, with 120; the Royal City of Dublin Hospital, with 124; the Adelaide Hospital, with 140; the Royal Victoria Eye and Ear Hospital, with 100 beds; Sir Patrick Dun's, which has a direct connexion with the School of Physic, and the combined institutions formed by the Hardwicke Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 230 beds.

As for the famous Dublin medical institution known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynaecological hospital in the British Isles. It receives nearly 3,000 patients every year, and, apart from ordinary out-patient work of a gynaecological order, annually attends some 2,000 women at their own homes during their confinement. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to medical graduates of any nationality.

BELFAST.

THE Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in connexion with the departments of biology, chemistry, physiology, pathology, anatomy, physics, and materia medica are all excellent, and there is a Students' Union which gives students the advantages of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 300 beds, and the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the university are: The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital; the Benn Ulster Eye, Ear and Throat Hospital; the Union Infirmary and Fever Hospital; the Fever Hospital, Pardysburn; the District Lunatic Asylum; the Samaritan Hospital, Forster Green Hospital for Diseases of the Chest, and the Belfast Hospital for Skin Diseases.

Scholarships.—(1) Twelve, of the value of £40 each, are assigned as Entrance Scholarships in the Faculties of Arts, Science, and Medicine, tenable for one year; (2) sixteen Professional Scholarships, value from £15 to £40 each; (3) one Hutchinson Stewart Scholarship, £12, in mental diseases; (4) one Mackay Wilson Travelling Scholarship, £100, awarded triennially; (5) Isabella Tod Memorial Scholarship, tenable for three years, awarded triennially to a woman student; (6) Magrath Clinical Scholarship, awarded annually, value about £112; (7) two Musgrave Studentships of £200 in Physiology and Pathology; (8) numerous seasonal prizes. There is also a post-graduate research fund, open to all graduates of not more than three years' standing. Gold medals are awarded at the M.D. examination.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £150. This includes examination fees and a place at the Royal Victoria Hospital, and fees for the special amount. The Conjoint Board costs about the same

amount.

The Calendar containing full information can be obtained on application to the Secretary, Queen's University, Belfast, price 2s.

UNIVERSITY COLLEGE, CORK.

This institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the National University. It holds open all the facilities of that city, in the work which it has to perform, namely, that of providing education

adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the new university, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmarys (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (60 beds), the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The session extends from October to June.

There is a Dental School in which the degree of Bachelor of Dental Surgery of the National University of Ireland can be obtained. There is a large well-equipped Dental Hospital in connexion with the school.

Scholarships.—Over £4,000 are available annually for scholarships in the College. Particulars as to each of them can be obtained on application to the Registrar.

Fees.—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees, come to about £120.

Further information can be found in the college regulations, or obtained on application to the Registrar.

UNIVERSITY COLLEGE, GALWAY.

THIS institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Art, Science, Celtic, Engineering, Commerce, and Medicine. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library, a college union, and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students, in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University but for those of London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Galway County Hospital, the Galway Union Hospital, the Galway Fever Hospital, and the Galway Dispensaries. The Galway County Hospital is a general hospital, and at the other two hospitals, and at the dispensaries students have ample opportunities of studying zymotic and chronic diseases. The Union Hospital has a special ward for diseases of children. Each year the governing body offers about £1,500, and the County Councils of Connaught offer about £3,500, in scholarships. These scholarships are tenable in any faculty. Additional information regarding these scholarships can be obtained on application to the Registrar, and to the Secretaries of the Connaught County Councils.

CLINICAL HOSPITALS IN ENGLAND.

THERE are a great many hospitals in Great Britain and Ireland which, though not connected with any medical school, open their doors either to those who have yet to become qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving such instruction as opportunity offers, and at those situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments for resident medical officers, house-physicians, and house-surgeons. These are usually paid offices, which may be held for periods varying from six months to a year. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities, but it should be added that there are many other provincial hospitals where admirable work is done, and at which much valuable experience can be gained by both senior and junior students, and by

those already qualified. Cases in point are the Royal Infirmary, Bradford; the Royal Sussex County Hospital, Brighton; the Royal United Hospital, Bath; the Kent and Canterbury Hospital; Derbyshire Royal Infirmary; the Royal Albert Hospital and Eyo Infirmary, Devonport; the Royal Devon and Exeter Hospital; the West of England Eye Infirmary, Exeter; the Gloucestershire Royal Infirmary and Eyo Institution; the Royal Infirmary, Leicester; the County Hospital, Lincoln; the General Hospital, Northampton; the Norfolk and Norwich Hospital; the General Hospital, Nottingham; the Royal Portsmouth Hospital; the Royal Berks Hospital, Reading; the Royal South Hants and Southampton Hospital; the Staffordshire General Infirmary, Stafford; the North Staffordshire Infirmary at Hartshill; the Royal Hants County Hospital, Winchester; the Wolverhampton and Staffordshire General Hospital; the County Hospital, York; and the Coventry and Warwickshire Hospital.

London Clinical Hospitals.

As for hospitals in the metropolis, so many of these take a share in the giving of clinical instruction that it is worth while to classify them.

General Hospitals.—These include the Dreadnought Hospital at Greenwich, and its annex at the Albert Dock, which form the headquarters of the London School of Clinical Medicine, and the London School of Tropical Medicine with its hospital at Endsleigh Gardens; the West London Hospital and the Prince of Wales's General Hospital, Tottenham, both of these being described in the article on the Royal Northern Hospital, Holloway Road, 185 beds; and the Temperance Hospital in Tottenham.

Children's Hospitals.—There are at least seven of these, the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 240 beds. There are also the East London Hospital for Children, Shadwell, with 124 beds; the Queen's Hospital for Children, Bethnal Green, with 134; the Victoria Hospital for Children, Chelsea, with 100 beds; the Hospital for Children, which has a considerable out-patient department; the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds.

Hospitals for Women.—Queen Charlotte's Lying-in Hospital, Marylebone Road, with 70 beds and a residential college for students and nurses in the teaching of midwifery. The hospital admits qualified patients and nurses, and the fees—payable in advance—being £3 ss. for three months; full particulars may be obtained from the Secretary, the Hospital for Women, 100, Strand, London, W.C.2.

Women in London Road, the latter being in the nature of a general hospital so far as the treatment of cases is concerned.

Eye Hospitals.—These are the Royal London Ophthalmic Hospital, City Road. At this hospital two complete courses of instruction are given during the year—October to February and March to July—comprising the following subjects: anatomy, physiology, and optics; ophthalmic medicine and surgery—(1) external diseases, (2) internal diseases, (3) ophthalmoscopic conditions (weekly practical refraction classes; methods of operative surgery; practical pathology; x-ray and radiotherapy; clinical lectures; discussion classes. A fee of 24 guineas entitles the student to a five months' course (with the exception of bacteriology), together with a practical certificate. The fee for the permanent certificate is £5 ss.; for three or six months, £3 ss.; for two months, £2 ss.; for one month, £1 ss. Gentlemen are eligible, under certain conditions, for the posts of chief clinical assistant, clinical assistant, and junior assistant. Clinical work takes place every morning at 9 o'clock, and operations at 10 every morning. An additional special course in the preliminary subjects (namely, anatomy, physiology, and optics) for the D.O.M.S., and other ophthalmology examinations, will be held immediately preceding the date of the examination. The fees for this course will be 12 guineas, or £5 ss. for any subject separately. Further particulars may be obtained from the Dean of the Medical School. Other eye hospitals are the Royal Westminster Ophthalmic Hospital near Charing Cross, the Royal Ophthalmic Hospital, the Central London Ophthalmic Hospital, and the London Ophthalmic Hospital. The Board has under its control the treatment of the more serious zymotic disorders; it makes special arrangements for the instruction of students in this subject, and grants certificates at the end of the courses. Detailed particulars may be obtained from the Clerk to the Board, Victoria

Royal Hospital for Diseases of the Chest, City Road, which has recently decided to become amalgamated with the Royal Northern Hospital, Holloway Road.

Nose, Throat and Ear Hospitals.—The institutions which confine their work to disorders of the throat, nose and ear all make special arrangements for the benefit of senior and post-graduate students. They are the Metropolitan Ear, Nose and Throat Hospital, Fitzroy Square; the Royal Ear Hospital, Dean Street; the Central London Throat, Nose and Ear Hospital, Gray's Inn Road; and the Hospital for Diseases of the Throat, Golden Square—the latter, which possesses 75 beds, being the largest of the four institutions.

Miscellaneous Special Hospitals.—Among these are the Bethlem Royal Hospital, St. George's Fields, S.E.1, which confines its work to the treatment of mental diseases, and includes a department for nervous and early mental disorders; St. Peter's Hospital for Stomach and Urinary Diseases, Henrietta Street, Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; the National Hospital for Diseases of the Heart in Westmoreland Street, W.1; St. John's Hospital for Diseases of the Skin, in Leicester Square; the Hospital for Diseases of the Skin, Stamford Street, Blackfriars; and the National Hospital for the Paralyzed and Epileptic, Queen Square, W.C.1, an institution possessing 200 beds and a world-wide reputation.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

MEDICAL EDUCATION OF WOMEN.

WOMEN are admitted to all the medical examinations of the following qualifying bodies: all the Universities of Great Britain, with the exception of Cambridge; the Royal College of Physicians of London and the Royal College of Surgeons of England; the Society of Apothecaries of London; the Conjoint Boards of Scotland and of Ireland. The regulations of the various universities and colleges and those of the General Medical Council set out above apply to women in the same way as to men.

The schools which admit women only are the London (Royal Free Hospital) School of Medicine for Women, which is one of the constituent schools of the Medical Faculty of the University of London. Glasgow University (see p. 436) has Queen Margaret College for the use of students of the University, and where some of the classes are restricted to women, such as practical anatomy. The clinical classes and university lectures in the Royal Infirmary are open to students of both sexes. Women are also admitted to the schools of medicine in connexion with King's College, Charing Cross Hospital, and St. Mary's Hospital, London, and in restricted numbers to University College Hospital Medical School. The medical schools of the English, Scottish, and Irish Universities and Colleges are open to women. The arrangements for women students in Edinburgh are indicated on page 435. Women enrolled in this university are, however, not guaranteed a course in Practical Obstetrics in the Maternity Hospital. Women can also attend the medical school attached to University College, Cardiff. As regards the London School of Medicine for Women, particulars will be found at page 431 in the article on London Medical Schools.

Women hold many appointments as residents in general hospitals, in hospitals for women and children, and in a large number of sanatoriums, infirmaries, fever hospitals, and asylums. Many medical women are also engaged in public health, tuberculosis, and school inspection work, as well as at infant welfare centres and venereal disease clinics; they can also become prison medical officers and inspectors of the mentally deficient.

In view of the very great increase during the past seven years in the number of women medical students it may, perhaps, be well to direct the attention of those who contemplate entering the profession to the word of caution given in our introductory article on the Profession of Medicine. It is desirable that women who contemplate the study of medicine should reflect carefully on the keen competition for posts which has existed since the war, and when qualified, consider the wisdom of seeking a wider field than hitherto in general practice and specialization, more especially in obstetrics and gynaecology. There is a large field opening in India, both in practice and the women's services in that country.

The British Medical Association was the first of all professional organizations to lay down the principle that no distinction should be made on the ground of sex as regards the emoluments to women members of the profession. In its constant efforts to maintain this principle the Association works in close co-operation with the Federation of Medical Women. In defence of the principle the Association has at

largest of these is the Brompton Hospital

has 333 beds and a large sanatorium at

There is also the City of London Hospital

for Diseases of the Chest, Victoria Park, with 175 beds, and the

various times fought—usually with success—Government departments and local authorities of all kinds. Where the authorities concerned have declined to recognize the justice of the claim that equal pay should be given for equal work the machinery, local and central, of the Association has been put into operation, and as a result the authority has generally seen fit to drop the proposed distinction between men and women practitioners or give up the attempt to fill the post.

DEGREES FOR PRACTITIONERS.

At one time it was almost the universal custom for medical students educated in London and aiming at general practice not to seek a university degree, and as that custom still prevails to a considerable extent a large proportion of medical men in England possess diplomas or licences to practise but not degrees in medicine. This is a fact which they sometimes find reason to regret, and to such practitioners the following paragraphs may be of interest. It should be noted, however, that the M.D. degree of the University of Brussels, if obtained subsequently to June, 1886, is not registrable, and that the University authorities have decided to discontinue granting it under special conditions to foreign medical practitioners from Great Britain and British Dominions.

UNIVERSITY OF LONDON.

Registered medical practitioners who have passed the First Examination for medical degrees and the Second Examination for medical degrees, Part I, may proceed to the Second Examination for medical degrees, Part II, and M.B., B.S. Examinations without observing the intervals prescribed by the regulations, on producing certificates that they have gone through the required course of study at a school of the university; subject to the proviso that no degree of the university can in any circumstances be granted by examination to anyone in less than three years after passing the Matriculation Examination or after admission by the university of the candidate's right to exemption therefrom.

UNIVERSITY OF DURHAM.

The degree of M.D. is granted by the University of Durham to registered practitioners of not less than fifteen years' standing, who have been qualified and in practice for that period, upon the following conditions without residence: The candidate must be 40 years of age, and must produce a certificate of moral character from three registered medical practitioners. Should he not have passed an examination in arts previously to the professional examination in virtue of which his name was placed on the *Register*, he is examined in classics and mathematics; if otherwise, he is required to translate into English passages from any one of the following Latin authors: Caesar, *De Bello Gallico* (first three books), Virgil, *Æneid* (first three books), or Celsus (first three books). Natives of India or the British Colonies are placed on the same footing as natives of Great Britain. Natives of India must produce evidence from an Indian university that they have passed within one year an examination in Latin.

Professional Examination.—The candidate must pass an examination in the following subjects: (i) Principles and practice of medicine, including psychological medicine, hygiene, and therapeutics; (ii) principles and practice of surgery; (iii) midwifery and diseases of women and children; (iv) pathology, medical and surgical; (v) anatomy, medical and surgical; (vi) medical jurisprudence and toxicology. The examination is conducted by means of printed papers, clinically, and viva voce, at the Colloquio of Medicine, Northumberland Road, Newcastle, and in the Royal Victoria Infirmary. The classical part of the examination may be taken separately from the professional on payment of a portion (£10 10s.) of the full fee.

The examinations are held twice a year, towards the end of March and of June. Notice, accompanied by the fee and certificates, must be sent to Professor Howden, Registrar of the University of Durham College of Medicine, Newcastle-on-Tyne, at least twenty-eight days before the commencement of the examination.

Fees.—The inclusive fee is 50 guineas; if a candidate fail to pass, 20 guineas are retained, but if he present himself again, 40 guineas only are required.

UNIVERSITY OF BRUSSELS.

Until recently this university granted its M.D. degree to such foreign candidates as were already duly qualified in medicine and surgery in their own countries, provided they

passed the three examinations imposed. The examinations were conducted solely viva voce and in English. The secretary of the University of Brussels, however, announced last year that these special examinations will no longer be held, nor will the diploma of the degree be granted by the university to foreign medical practitioners as formerly. It is understood that the university authorities have decided that all foreigners seeking medical degrees shall be called upon to fulfil the same requirements, and that special privileges cannot henceforward be conceded to practitioners from Great Britain and the British Dominions.

POST-GRADUATION STUDY.

MANY facilities for post-graduate study already exist in London and in certain other centres. In London the real difficulty has been that the facilities have not been co-ordinated, and that only lately has it been possible for a graduate wishing to join classes in London to learn where he could obtain instruction in the subject in which he was particularly interested. The difficulty has been the greater because formerly very little attempt was made to discriminate between the two main classes of post-graduate students—those who desire advanced or special courses, either for the purpose of "finishing" their medical education or acquiring knowledge of the technique of special subjects, and those who, having been in practice for some years, desire to revise or increase such general medical knowledge as is useful in their professional work. For the latter class the courses now given at the West London Hospital Post-Graduate College and the North-East London Post-Graduate College are eminently suitable; some of the large undergraduate teaching hospitals provide short post-graduate courses for their former students during the summer vacation, and at the Charing Cross Hospital arrangements have been made with the London Panel Committee whereby weekly post-graduate instruction is given to insurance practitioners.

Towards the end of 1918 the Fellowship of Medicine was founded in London. Its object was to draw together the members of the medical profession of all the inter-allied countries for the exchange of medical knowledge and the advancement of medical science. An emergency post-graduate course was arranged in the early part of 1919 for the benefit of medical men who had served as temporary officers of the Navy, the R.A.M.C., the Royal Air Force, and of the Dominions, the United States, and the allied countries. The teaching schools in the metropolis co-operated in the course, and daily lectures and demonstrations on general and special subjects were given.

Proposals for a permanent post-graduate organization in London had been put forward by the Post-Graduate Medical Association, and in October, 1919, this body and the Fellowship of Medicine were amalgamated. After the matter had been fully discussed, and after the amalgamated body had learnt a good deal from experience, it resolved to make representations to the Government, and in response to these the then Minister of Health, Dr. Christopher Addison, appointed a committee under the chairmanship of the Earl of Athlone. This committee recommended that a school attached to a hospital centrally situated in London should be devoted solely to post-graduate medical education, that it should be a school of the University of London, and that it should receive financial assistance from Parliament. After indicating how the school should be organized, the committee went on to advise that an Institute of State Medicine should be organized in London to give instruction in public health, forensic medicine, industrial medicine, and medical ethics and economics. This last recommendation is about to be realized, owing to the munificent gift by the Rockefeller Institute of two million dollars to defray the cost of building and equipping an Institute of Hygiene. When accepting the offer on behalf of the Government the Minister of Health undertook to provide £25,000 a year for upkeep. A site has been acquired in Bloomsbury, the district which it is hoped may become the university quarter of London; but it must be two years or more before the buildings can be available for research and teaching.

With regard to the other recommendation of the Athlone Committee no definite progress has yet been made. The Fellowship of Medicine continues to arrange courses of post-graduate instruction in London of various kinds, and its monthly *Bulletin* contains a list of many hospitals which welcome the attendance of graduates. By the

kindness of the Royal Society of Medicine the Fellowship of Medicine has its offices in the Society's house, 1, Wimpole Street, W.1; and there the inquirer will obtain information as to classes and clinical practice which may be open to him at the time of his visit to London. Last July the Fellowship took the initiative in sending a deputation to the Minister of Health to urge on him the expediency of helping to realize the recommendation of the Athlone Committee with regard to the establishment of a post-graduate school and hospital in London. The deputation received an ambiguous but on the whole encouraging and sympathetic reply. There for the moment the matter stands.

Nevertheless, the graduate who visits London will find that many opportunities are at his disposal. For ophthalmic work Moorfields Hospital and the Royal Westminster Ophthalmic Hospital are available. Practical work in diseases of the throat, nose, and ear is obtainable at the Hospital for Diseases of the Throat, Golden Square, and intensive courses, as well as three-monthly attendances in the practice of the hospital, exist at the Central London Nose, Ear, and Throat Hospital, Gray's Inn Road. At the Brompton Hospital for Consumption there are many post-graduate students. The Hospital for Women, Soho Square, has special courses lasting six weeks, and clinical assistantships are available at the Samaritan Free Hospital for Women. At the Hospital for Diseases of the Skin, Blackfriars Road, demonstrations are given daily, and there are similar demonstrations and a course of lectures during the winter months at the St. John's Hospital for the Skin. Post-graduate instruction in the diseases of children is given at the Hospital for Sick Children, Great Ormond Street, and at the Paddington Green Children's Hospital. At the London Hospital there is a six months' course for school medical officers (actual and intending), and for general practitioners who desire to undertake the work of school clinics. The opportunities afforded in London to prepare for the diplomas in psychological medicine are mentioned in the article on that subject (p. 443).

This is very far from being a complete list of the facilities existing in London; it will serve as a general indication, to be expanded by reference to the following paragraphs and to the *Bulletin* of the Fellowship.

Post-graduate courses are held at Oxford, Manchester, Birmingham, and Bristol. In Scotland post-graduate courses in Edinburgh are conducted by the teachers of the University and Royal Colleges; and in Glasgow post-graduate medical association has been formed under the management of the post-graduate teachers and of representatives of the institutions granting facilities for instruction.

In Wiltshire and the neighbouring counties an interesting experiment is in progress, under which members of hospital staffs in Bristol visit various centres and lecture to the local practitioners. Post-graduate instruction of a somewhat similar character is given in South-West London, where members of the staff of the Brompton Hospital give demonstrations and lectures at the St. James's Municipal Hospital, formerly the poor law infirmary.

The remarks above refer almost entirely to comparatively short courses, in the nature of revision classes. This country has not so far followed the example of America in establishing long courses extending into years, with a view to making men specialists in the various branches. It is questionable whether any attempt in this direction will be made in this country, where such training is usually obtained by holding junior appointments such as that of clinical assistant.

* FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.

The Fellowship has arranged with the medical schools in London and other hospitals for a post-graduate course admitting to their general practice, including clinical instruction in the wards and out-patient departments, clinical lectures and demonstrations, post-mortem demonstrations, laboratory work, etc. Tickets can be obtained from the Secretary at the rate of one month, 6 guineas; two months, 10 guineas; three months, 13 guineas; six months, 18 guineas; and one year, 20 guineas. They admit the holder to certain of the London hospitals to which medical schools are attached, and to a large number of other London hospitals and institutions. The Fellowship issues a monthly bulletin containing a programme of the work in these hospitals, specifying the names of teachers or lecturers, together with the time and place at which their instruction is given. This list is arranged under the headings of the various sections of the course—for example,

diseases of the chest, ophthalmology, radiology, venereal diseases, etc. There are also occasional short courses in general and special subjects; notice of which is given in the *Bulletin* and issues of the *BRITISH MEDICAL JOURNAL*. Announcement is also made of special courses of clinical lectures, some of which are occasionally held out of London.

The offices of the Fellowship are at 1, Wimpole Street, W.1 (telephone Mayfair 2236). The Secretary, Miss M. A. Willis, is in attendance daily from 10 a.m. to 5 p.m., excepting Saturday. The annual subscription for membership of the Fellowship of Medicine and Post-Graduate Medical Association has been fixed at a minimum of 10s.

EDINBURGH POST-GRADUATE COURSES IN MEDICINE.

In connexion with the University and Royal Colleges Post-Graduate Courses have been arranged this year from July 31st to September 9th inclusive, comprising: (a) A Course on Diseases of Children from July 31st to August 11th; (b) a General Medical Course; (c) a General Surgical Course. Courses (b) and (c) will extend for four weeks from August 14th to September 9th.

The Course on Diseases of Children will include Medical and Surgical Clinics and Special Clinics on Diseases of the Skin, Venereal Diseases, Child Welfare, Mental Defect, Ear and Throat, Dental Clinics, and Ante-natal Clinics. The General Medical Course will include Lecture Demonstrations, and, where possible, practical instruction on Medical Anatomy, Medical Side-room Work, Examination of the Blood, X-Ray and Electrical Therapy, Morbid Anatomy, and Post Mortems; Clinical Instruction in Medicine, Diseases of Children, Diseases of the Skin, and Infectious Diseases; and Special Instruction in the Diseases and Methods of Examination of the Nervous, Circulatory, Respiratory, Alimentary, and Renal Systems, and in Diseases of the Ductless Glands. The General Surgical Course will include Lecture Demonstrations on Surgical Anatomy, Surgical Pathology, and Surgical X-Ray Diagnosis; Clinical Instruction in Surgery at the Royal Infirmary and Royal Hospital for Sick Children; Clinical Instruction in Venereal Diseases; Surgical Out-patients; Surgical and Gynaecological Operations and Special Instruction in Abdominal and Genito-Urinary and other branches of Surgery.

A series of Special Lectures, open to all graduates, will be delivered thrice weekly during the month, on subjects of general Medical and Surgical interest, including recent advances in treatment. The following have also been arranged: Examining Therapeutics, Physiological and Biochemical Methods in Clinical Medicine, Diseases of the Ear, Nose and Throat, and Venereal Diseases.

Particulars regarding the courses, dates of commencing, fees, etc., may be had on application to the Honorary Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

GRADUATE MEDICAL TEACHING IN GLASGOW.

Organized post-graduate medical teaching is available in Glasgow under the auspices of the Post-Graduate Medical Association. This association is composed of practically all the teaching institutions in Glasgow and the various teachers giving post-graduate instruction, and its business is managed by a board elected periodically by them. The chairman of the board is Principal Sir Donald MacAlister, K.C.B., M.D., and the vice-chairman Sir Hector C. Cameron, C.B.E., M.D. During the winter months special courses in various subjects are conducted, and there is a series of weekly demonstrations specially designed for local practitioners. A comprehensive scheme of Clinical Courses is carried out during the summer months, from May till October, and arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Those desiring further information should apply to Dr. J. N. Cruickshank, Acting Secretary, Post-Graduate Medical Association, University, Glasgow.

COURSES FOR MEDICAL GRADUATES AT BRISTOL.

The University of Bristol provides courses of post-graduate study for practitioners. Details of set courses at the Royal Infirmary and General Hospital are announced locally. In addition, practitioners may become clinical assistants in

medicines, surgery, or special subjects for periods of a month or more.

The University also holds courses of demonstrations in outlying centres in the West of England. Resident practitioners form themselves into a committee and consider the type and extent of demonstrations required. The University furnishes the lecturers and makes all the necessary arrangements.

All inquiries should be addressed to the Director of Post-Graduate Studies, Pathological Department, Bristol University.

WEST LONDON POST-GRADUATE COLLEGE.

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895; it is provided with lecture, reading, writing, and class rooms, and accommodation of all sorts for the convenience of post-graduate students. In the five years before the war the yearly entry averaged over 220. The work of the college is eminently suitable for men who wish to revive their general clinical knowledge after war work.

As for ward work, the students accompany the senior staff on their visits to the wards at 2.30 p.m. daily, and also go round with the resident medical officers in the morning. Out-patient work begins at 2 p.m. This department is large, and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments. Post-graduates are appointed to act as clinical assistants for three or six months. There is no charge to members of the college. Special practical classes are held in medicine, general practical surgery, gastro-intestinal surgery, medical and surgical diseases of children, analysis of blood and urine, cystoscopy, venereal disease, tropical diseases, retinoscopy, ophthalmic operative surgery, and, when material is available, in operative surgery. The size of the classes is limited. A special clinic for the treatment of venereal diseases (male and female) is held every evening (Saturdays included) at 5.30. Graduates are admitted to the work of the clinic free, and certificates of satisfactory attendance and work are given.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the post-graduates, and in any case making arrangements so that they can readily see what is going on. The anaesthetists give instruction in the administration of anaesthetics, including spinal analgesia, on the operating days, students being allowed to administer them under supervision, while special classes are held in each session. The pathological laboratory is in charge of a pathologist who attends every day.

Demonstrations are ordinarily given in the morning by the assistant physicians and surgeons, and by the medical and surgical registrars. Lectures of a practical kind are given daily.

Fees.—Hospital practice, including lectures, £1 11s. 6d. for one week, £6 6s. for six weeks, £9 9s. for three months, £23 12s. 6d. for one year, and £45 for a year and a half. August there is a special vacation, which the fee is £1 14s. 6d. Instruction in the administration of anaesthetics is given at the rate of £3 3s. a month.

The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, and the University of London (for higher degrees). A prospectus can be obtained on application to the Dean.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.

The headquarters of this post-graduate school are situated at the Prince of Wales's General Hospital, in the midst of a densely populated North London district. It contains 125 beds, and is within a few minutes' walk of South Tottenham Station on the Midland Railway, Seven Sisters Station on the Great Eastern Railway, and Tottenham Hale on the Great Eastern main line. It is readily accessible by electric tram from Finsbury Park and Hackney, and from Dalston, Edmonton, and other parts of North London.

The college is recognized by the Admiralty and the India Office for the purposes of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees; the course of practical teaching of bacteriology is approved by the University of Cambridge for its D.P.H. Diploma, and there are ample arrangements for the convenience of men who are thus working, or who, being in active practice, are desirous of getting themselves into touch

with modern methods. The hospital as a whole affords excellent facilities to qualified medical practitioners who wish to take part for a time in the work of an active general hospital, or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, radiography, the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions into which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff in the lecture room. Operations are performed every afternoon of the week except Saturday. Special classes are arranged in modern methods of the investigation and treatment of disease, and special intensive courses are held at intervals throughout the year, each lasting two weeks, clinical instruction being arranged for each hour of each day.

Fees.—The department admits to a course of study in any one year; a fee of 5 guineas for a similar term (one month, 2 guineas, and one year, 10 guineas), and a perpetual ticket for the practice of the hospital may be obtained for 15 guineas.

Additional information can be obtained from the Dean of the Post-Graduate College, at the hospital, or at 19A, Cavendish Square, London, W.1.

AUSTRALIAN AND NEW ZEALAND MEDICAL ASSOCIATION.

Some members of the profession born in Australia or New Zealand, and now resident in England have formed an Australian and New Zealand Medical Association to give information and advice to medical visitors from the Commonwealth and Dominions with regard especially to attendance at special clinics, post-graduate work, and facilities for preparing for examinations such as the M.R.C.P., F.R.C.S. (England and Edinburgh), and the D.P.H., and also as to house appointments and clinical assistantships in London and the provinces. Information will also be given as to lodgings, sports, and social opportunities. All medical graduates or undergraduates born in Australia or New Zealand and resident, or visiting England are eligible to become members. The fee is one payment of 5s. Further information can be obtained from the joint honorary secretaries, Mr. E. T. C. Milligan, F.R.C.S., and Mr. Bedford Russell, F.R.C.S., 86, Harley Street, London, W.1.

TROPICAL MEDICINE.

There are large and important schools of Tropical Medicine in London and Liverpool, and several universities and other examining bodies have instituted diplomas or degrees in the subject. The Colonial Office now expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees follows.

DIPLOMAS AND DEGREES.

LONDON UNIVERSITY.—Tropical medicine is one of the six branches in which the M.D. degree may be obtained. The regulations relating to the curriculum and examination correspond to those applying to the other branches.

LONDON JOINT BOARD.—This body grants a diploma in tropical medicine to candidates after an examination usually held in the months of April, July, and December. Ordinary candidates must present evidence of having attended, subsequently to obtaining a registrable qualification in medicine, surgery, and midwifery, (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine, in an institution recognized for this purpose, during not less than three months; (2) the clinical practice of a hospital recognized for the study of tropical diseases during not less than three months. These conditions may be modified in the case of candidates who have had practical experience in tropical countries. The fee for admission to the examination is £9 9s. The Board also grants diplomas in psychological medicine and in ophthalmic medicine and surgery. Candidates must hold a medical qualification registrable in the United Kingdom or be graduates in

medicine of an Indian, Colonial, or foreign university. Particulars and conditions of admission to these examinations, fees, etc., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen Square, Bloomsbury, London, W.C.1.

UNIVERSITY OF LIVERPOOL.—A diploma in tropical medicine is given by this university to students who have been through the courses provided by the Liverpool School of Tropical Medicine and have passed the examination held twice yearly by the university examiners. The subjects of examination are (a) tropical pathology, and entomology; (b) tropical and sanitation; (c) tropical hygiene and sanitation; (d) tropical medicine, including etiology, symptoms, diagnosis, and treatment of tropical diseases. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF CAMBRIDGE.—This university grants a diploma in tropical medicine and hygiene to any person whose name has been on the *Medical Register* for not less than a year provided that he passes the examination of the university in this subject. Previous to admission to the examination he must produce approved evidence that he has studied pathology (including parasitology and bacteriology in relation to tropical diseases), clinical medicine and surgery at a hospital for tropical diseases, and hygiene and methods of sanitation applicable to tropical climates. Examinations are held in January and August each year, and last four days. The fee for the examination and diploma is 9 guineas on admission or readmission. Application for further information should be made to Dr. G. S. Graham-Smith, Pathological Laboratory, Cambridge.

SCHOOLS.

LONDON SCHOOL OF TROPICAL MEDICINE.

This school is under the auspices of the Seamen's Hospital Society. The laboratories, museum, library, etc., are within the building of the Hospital for Tropical Diseases, Endsleigh Gardens, N.W.1, and excellent opportunities are afforded to students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. In the wards of the Hospital for Tropical Diseases are to be found cases of tropical disease such as may be met with in actual practice in the tropics. There are three courses in the year, lasting three months, beginning September 25th, January 9th, and April 24th approximately. The course is so arranged as to equip men for the Cambridge D.T.M. and H. and the D.T.M. and H. of the Conjoint Board. Tropical Medicine has been admitted as a sixth alternative subject for the M.D. of the University of London, and the school curriculum is adapted to afford facilities for candidates desirous of taking out the M.D. in this subject. Further information may be obtained from the Dean, London School of Tropical Medicine, India Office, Whitehall, London, and the Secretary, London School of Tropical Medicine, Seamen's Hospital, Greenwich, S.E.10.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

This school is affiliated with the University of Liverpool and the Royal Infirmary of Liverpool. Two full courses of instruction are given every year, commencing about January 6th and September 15th, lasting for the term of about thirteen weeks, and followed by the examination for the diploma of tropical medicine given by the University of Liverpool. Two courses in veterinary parasitology are also given, commencing about the same dates as the diploma courses. In addition to the full courses, an advanced course of practical instruction in tropical pathology and medical entomology, lasting a month, is given every year in June; it is of such a kind as to be very useful to medical men returning from the tropics on short leave. A special course of instruction in entomology, etc., is also given three times a year to officers of the East and West African Colonial Services. Students of the school who do not care to undertake the examination held by the university at the end of each term for the diploma in tropical medicine are given a certificate for attendance if the latter has been satisfactory.

Fees.—The fee for the full course of instruction is 20 guineas, with an extra charge of 1 guinea for the use of a microscope, if required. The fee for the Diploma Examination is 5 guineas, for the Advanced Course 6 guineas, and for the course in veterinary parasitology 15 guineas.

The new laboratories of the school adjoin the university and the tropical ward of the Royal Infirmary. The dimensions of the building are 162 ft. in maximum length by 84 ft. in width. In addition to the basement, in which are accommodated the photographic department and large storage rooms, there are four floors. The ground floor has: (1) Lecture theatre, with accommodation for about seventy students; (2) library; (3) a spacious museum, with preparation room adjoining. The first floor has twelve rooms, in which are housed the Departments of Tropical Medicine and Entomology. The second floor has the main class laboratory, 69 ft. by 58 ft., excellently lighted, and three other rooms, devoted to the Department of Parasitology. The third floor has a large research laboratory and two research rooms. On the roof is an insectarium, a mosquito-proofed house, and other accommodation.

Since it was instituted the school has dispatched to the tropics thirty-two scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-two special memoirs, besides textbooks and numerous articles in the scientific press, also in the *Annals of Tropical Medicine and Parasitology* of the school. In connexion with the school are (1) the Maudsley Research Laboratory in Brazil, and (2) the Sir Alfred Lewis Jones Tropical Laboratory, Sierra Leone, which was opened on January 10th, 1922. Further information may be obtained from the Hon. Doan, School of Tropical Medicine, Pembroke Place, Liverpool.

PSYCHOLOGICAL MEDICINE.

The study of mental diseases has been somewhat neglected in the past, and its importance has been scarcely recognized by the student as it has received so little emphasis in his medical curriculum. Of late years, however, it has become apparent that mental disorder constitutes a social and medical problem of great significance, and there is little doubt that in the future it will be recognized as one of the most important specialties. It should be understood that by mental disorder is not only meant those severe forms which are to be found in the asylums, but the term also includes the mental defectives of all grades, the mild and often unrecognized psychoses, and also the various types of psychoneuroses. The student who proposes to go into general practice should therefore make every effort to acquire a knowledge of mental disorder, and those who intend to take up a career in the prison service or, still more importantly, the school medical service, will find such knowledge an almost essential part of their equipment.

Instruction and Diplomas.

The facilities for the study of psychological medicine are now much greater than in former years. Most of the teaching hospitals have out-patient departments for the treatment of mental disorder, and in many of these hospitals special lectures are devoted to this branch of medicine, in addition to the usual and compulsory courses in insanity. In London post-graduate courses of instruction of a comprehensive kind are given at the Maudsley Hospital and at Bethlem Hospital, and at the National Hospital for the Paralyzed and Epileptic, Queen Square, courses are arranged to meet the requirements for the diploma in psychological medicine in regard to nervous diseases. Courses in mental deficiency are arranged by the University of London. There are also post-graduate courses at the Universities of Edinburgh, Cambridge, Birmingham, Leeds, Manchester, Durham, and elsewhere. Those who are taking up psychiatry as a career will find it desirable to obtain a diploma in psychological medicine. Such a diploma is not at present compulsory for a permanent position on the staff of a mental hospital, but it will probably become so in course of time, just as it is now essential to obtain the D.P.H. if a career in public health is contemplated. Psychiatry is one of the branches of medicine which candidates for the M.D. degree of the Universities of London and Edinburgh can take up, and, in addition, diplomas in psychological medicine, to which reference has been made, can be obtained from the Universities of Cambridge, London, Edinburgh, Durham, Leeds, Manchester, and the National University of Ireland, and from the Conjoint Board in England. The Medico-Psychological Association of Great Britain and Ireland also grants certificates of proficiency after examination and encourages the study of psychiatry by the offer of prizes for original and research work.

Mental Hospital Appointments.
 Those who take up psychiatry as a career work as medical officers of public or private mental hospitals, or similar institutions. Except in the larger institutions, such as those under the control of the London County Council, where a number of the medical officers are allowed to live out if married, the medical staff are resident officers, having board, lodging, etc., either in the hospital itself or a residence in the grounds. Junior assistant medical officers receive about £300 to £400 per annum, and senior assistant medical officers about £500 to £700, in both cases with board, lodging, laundry, etc., in addition; if married, the board, etc., is commuted for cash. As the mental hospitals are under local control the salaries show considerable variation in different asylums. Medical superintendents, whose pay commonly ranges between £800 and £1,500 per annum, are provided with a house in the grounds of the hospital and draw various allowances. Since the passing of the Asylum Officers' Superannuation Act in 1909, all officers and others of the established staff of a public (county or borough asylum) mental hospital may retire at the age of 55 on a pension varying from one-half to two-thirds of the value of their pay and emoluments, or one-fifth for every year served, paying as contribution 3 per cent. of the value of their appointments annually. This very favourable prospect may not appeal to junior practitioners joining the services, but will eventually prove to be a valuable asset.

Prospects in the Public Service.

Appointments to the public mental hospitals are made by the Visiting Committees, and in most cases only the junior posts are open to those who have not had previous experience in psychiatry. Since the public mental hospital service is a local and, except indirectly, not an imperial one, the promotion tends to be slow and uncertain, and the higher positions are not always advertised and thus thrown open to competition. For this and other reasons mental hospital work has undoubtedly not been in favour with newly qualified men in years past, but the general conditions of service have tended to show a progressive improvement and will in all probability continue to do so in the future.

In March, 1920, the Board of Control did useful service by issuing to visiting committees of asylums a circular upon the three following matters: (a) The dearth of suitable applicants when vacancies occur for the post of assistant medical officer; and the probable causes thereof; (b) the need of provision or the more effective treatment upon modern lines of recoverable cases of mental disorder; (c) the necessity for raising the standard as to the training of existing and future assistant medical officers in asylum practice, and of affording facilities for such training.

Under (a) the Board of Control, after pointing out some of the disadvantages of the present state of affairs, made the following suggestions:

- (i) That an improvement be made in the salaries of the assistant medical officers, at least to such an extent that in the cases of all those who have been in the service above a certain number of years and are regarded as permanent officials, the salary should be reasonably sufficient for a married medical man, and that in the case of the deputy superintendent it should more closely approximate than at present to that of the superintendent.
- (ii) That, in the case of a permanent official, application for permission to marry be not required; that, according to circumstances, proper accommodation for a married man be provided, and that subject to rules approved by the Secretary of State for the protection of the patients, and with due regard to the proper administration of the institution, permission to live out may be granted.
- (iii) That to the title of assistant medical officer the words "and deputy superintendent" should be added to that of the one selected to be in charge during the absence of the medical superintendent.
- (iv) That the use of the title "senior assistant medical officer" should not be restricted as at present to the post of first assistant, but should be extended and be indicative of a certain standing and expert knowledge. By the adoption of this suggestion there would many asylums be two senior assistant medical officers, and perhaps even three or four in the largest asylums.
- (v) That except where there has been previous asylum experience, appointments to posts of assistant medical officers, and in the first instance be temporary in character.

Under (b) the Board suggested that the treatment of recent recoverable cases should be carried out by members of the medical staff conversant with modern methods, and that the number of the medical staff should be sufficient to ensure that one of them is required to undertake the treatment of more than fifty recent cases at any one time. Under (c) suggestions are made with a view to encouraging assistant medical officers to obtain a diploma or degree in mental diseases, including provision for study leave on full salary. The

attitude of the Board of Control is clearly shown in the following sentence:
 "If the welfare, treatment, and recovery of patients is not to be jeopardized and the study of mental diseases is not to lag behind the study of other branches of medicine, the Board feel the necessity of initiating measures to maintain progress and to secure the best possible treatment of the patients."

Readers who wish to go farther into this subject may be referred to an interesting paper by Dr. C. Hubert Bond in the *Journal of Mental Science* for January, 1920, in which he insisted on the need for mental clinics and schools of psychiatry, and reviewed the progress made towards realizing the measures, powerfully advocated in 1908 by Lieut.-Colonel D. G. Thomson, for supplying adequate instruction in the institutes and practice of psychiatry.

Both the British Medical Association and the Psychological Association are working separately and together to improve present conditions of service, and have, for example, already removed the "celibacy" objection to the service. The salaries have also been considerably increased, especially in the junior ranks, and contrast favourably with those which were paid before the war. During the next few years considerable progress may be anticipated in the conditions under which the insane are treated. The asylums will tend to develop an atmosphere approximating more closely to that of the general hospitals, and there is a strong impulse towards the creation of clinics, attached to general hospitals, for the treatment and study of mental disorder in its early stages. If these most desirable changes are brought about, the mental hospital service will become more attractive, and will afford greater opportunities for the medical graduate who proposes to specialize in psychiatry.

Finally, it may be said that while routine, administrative, and clerical work bulk largely in mental hospital duties, as they do in other public medical services, there is ample material, time, and scope for purely medical work and research—difficult as the subject may be—in psychiatry as one of the branches of medicine open to young graduates.

MAUDSLEY HOSPITAL, DENMARK HILL.

A number of courses of instruction for the Diploma in Psychological Medicine have been given at the Maudsley Hospital, the details of the last course being as follows: The course consisted of two parts, Part I being conducted by Sir Frederick Mott, Dr. F. Golla, and Dr. Henry Devine. Sir Frederick Mott gave eight lectures on the anatomy of the nervous system, followed by practical instruction and demonstrations on methods of staining nervous tissue. Dr. Golla gave eight lectures on the physiology of the nervous system, for mounting as a permanent collection. Dr. Devine gave eight lectures on the chemistry of the nervous system, followed by practical instruction and demonstrations on physiological chemistry (including the chemistry of the analysis, and gastric contents analysis), and practical physiology (including the recording of reflexes and tremors in man and the action of drugs on the autonomic system). Similarly, Dr. Devine gave eight lectures on psychology, followed by practical instruction and demonstration of psycho-physical methods and memory and intelligence tests. In Part II of the course Sir Frederick Mott gave six lectures on the pathology of mental diseases, including brain syphilis, its symptoms and treatment. Dr. Bernard Hart gave eight lectures on the psychoneuroses. Sir Frederick Mott and Dr. F. Golla gave twelve clinical demonstrations in neurology; the first six demonstrations were given by Dr. Golla at the Hospital for Paralysis and Epilepsy, Maida Vale. Dr. F. C. Shrubbsall gave eight lectures on the practical aspect of mental deficiency. Dr. W. C. Sullivan, medical superintendent of Broadmoor Asylum, gave six lectures on crime and insanity. Dr. C. Hubert Bond and Dr. E. Mapother gave a course of lectures on the differential diagnosis and treatment of mental disorders and the legal relationships of insanity. The fee for the whole course (Part I and Part II) was 15 guineas, or for either part separately 10 guineas; for one single series of lectures in Part I the fee was 4 guineas, and in Part II 2 guineas. Inquiries as to lectures, etc., should be addressed to the director of the pathological laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

BETHLEM ROYAL HOSPITAL.

A course will be held at Bethlem Royal Hospital, commencing on September 18th, of lectures and practical instruction for the Diploma in Psychological Medicine. It is proposed

in futuro to give two courses each year, an autumn session of intensive character, commencing in September, and completed in early December, and a spring session, commencing in the middle of January and completed in the middle of April. Each course consists of two parts: Part A includes lectures and demonstrations on the anatomy, histology, and physiology of the nervous system, with lectures on psychology and demonstrations in experimental psychology. Part B comprises lectures and clinical demonstrations in psychology, including lectures and demonstrations in the morbid anatomy of the nervous system, a series of lectures, with clinical demonstrations, on different branches of psychological medicine, and lectures, with clinical demonstrations, on mental deficiency. Entrants for the course who pay a composition fee of 15 guineas may, if due notice is given, attend either Part A or Part B of one course and postpone the other part until the next session. An entrant who wishes to attend one part only pays a fee of 10 guineas. An entrant who takes the complete course can attend the general clinical practice of the hospital on payment of 5 guineas for six months or 10 guineas for one year, but an entrant who does not take either part of the course and desires to attend the clinical practice of the hospital must pay a fee of 5 guineas for each three months of attendance. Further particulars may be obtained from the physician-superintendent, Bethlem Royal Hospital, S.E.1.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE.

A post-graduate course, which fulfilled the requirements of the regulations for the Diploma in Psychological Medicine in regard to instruction in nervous diseases, was held at the National Hospital for the Paralyzed and Epileptic, Queen Square, Bloomsbury, W.C.1, from May 15th to June 30th, 1922, and other courses will be duly announced. Dr. J. G. Greenfield delivered lectures on the pathology of the nervous system; Dr. Gordon Holmes, Dr. Hinds Howell, and Dr. Minnie Wilson lectured on the anatomy and physiology of the nervous system; Dr. W. J. Adie demonstrated methods of examination of the nervous system; out-patient clinics were held at the hospital on the afternoons of Mondays, Tuesdays, Thursdays, and Fridays; and clinical lectures and demonstrations were held on Wednesday afternoons. An inclusive fee of 10 guineas was charged for the whole course, but any part of the course could be taken separately at a special fee. A special arrangement was made for those unable to attend the whole course, and for details applications should be made to the dean of the medical school. Fees are payable to the secretary of the hospital on entering for the course.

PUBLIC HEALTH SERVICES.

GENERAL CONSIDERATIONS.

The Public Health Service, to use the term in a strict sense, consists of medical officers of health appointed by local public health authorities and holding office under varying conditions of tenure. In addition there are county medical officers appointed by the county councils. The latter are not, strictly speaking, public health authorities; the duties of their medical officers are somewhat similar to those of other medical officers of health, but include few executive functions. In many of the county boroughs and counties assistant medical officers of health or assistant county medical officers are appointed, and such appointments may afford stopping stones for promotion to higher offices. The service is, however, not unified throughout the country, and there is no regular system of promotion; appointments are to be obtained only by application to some particular local authority which has advertised a vacancy.

Three other services also ungraded have been brought into existence by recent legislation; their members are charged with duties which bring them into more or less direct relation with public health authorities or county councils and their officers. They are school medical officers, tuberculosis officers, and venereal disease medical officers. Appointments as school medical officer are made by local education authorities, while appointments as tuberculosis officer and venereal disease officer are made by the county councils and the county borough councils.

The medical department of the Ministry of Health for England has been organized under the control of a chief medical officer who has the status of an assistant secretary; it contains six sections, with a senior medical officer

at the head of each. These sections are concerned with general health and epidemiology, maternity and child welfare, tuberculosis and venereal disease, the supervision of food supplies, and sanitary administration in relation to infectious disease. There is a separate section concerned with insurance practitioners. Lastly, there are medical officers employed in the Poor Law department and several whose services are available for special purposes but who are not "established" officers. Medical officers and medical inspectors are also employed by the Ministry or the corresponding Board in Wales, in Scotland, and in Ireland. Appointments to these posts are not open to public competition; they are made by the Minister of Health in England and Wales and by the corresponding head of the department in Scotland and Ireland. They are civil service appointments, and come under the superannuation scheme of the service.

MEDICAL OFFICERS OF HEALTH.

The first appointments of medical officers of health were made for limited periods, the holder of the office having to risk re-election at the expiration of his term of office. This pernicious practice, so far as it applies to whole-time officers, owing to the persistent endeavours of the British Medical Association, in co-operation with some other bodies, ceased to exist after April 1st, 1922, as regards medical officers of health appointed prior to May 1st, 1921; it is not in operation as regards those appointed after the latter date. The Public Health (Officers) Act, 1921, which was promoted by the British Medical Association, provides that a whole-time medical officer of health shall not be appointed for a limited period, and shall not be removed from his office except with the consent of the Minister of Health. This Act came into operation on April 1st, 1922, but an order of the Minister of Health dated April 12th, 1921, makes a similar provision with respect to those officers appointed after May 1st, 1921.

A medical officer of health who does not devote his whole time to the duties of his office, and a portion of whose salary is obtained from Exchequer grants, may be appointed without limit of time, in which case he cannot be removed from office without the consent of the Minister of Health. If he is appointed for a specified term, say one year, he continues to hold office from year to year unless the Minister consents to his removal or the electing authority gives him three months' notice to resign his office, but the notice must take effect at the same period of the year as that at which the original term of appointment expired. Where the electing body pays the whole of the salary of a medical officer of health he may be dismissed from office without reference to the Minister of Health.

An increasing number of local authorities have established schemes for the superannuation of their officials, but there is no general scheme throughout the country. During the past twenty years the British Medical Association has on several occasions succeeded in getting introduced into Parliament a bill providing for the superannuation of medical officers of health, but the measure has always been opposed by the Government of the day, latterly on the ground that all municipal officers should be superannuated, and that sectional legislation was undesirable. In this connexion it may be stated in passing that medical officers of health are the only State-paid (whole-time) medical officers who do not come under a superannuation scheme.

A medical officer of health of a county or of a district or combination of districts with a population of more than 50,000 persons must hold a diploma in public health. This diploma is now generally required from all applicants for whole-time appointments of medical officers of health and assistant medical officers of health, and very frequently in the case of school medical officers, tuberculosis officers, and venereal disease officers. A medical man who desires to enter the public health service as a career must as a first step obtain such a diploma.

Position in Scotland.

The above statement applies specially to England. In Scotland the position is different in several respects. The central authority is a Board of Health which has at present five members, with offices in Edinburgh. One of the five is a medical man. It is now proposed to reduce the membership to three as existing appointments expire, but one of the three will be medical. The "Board" system is the rule in central government north of the Tweed, there being also Boards of Agriculture, Fisheries, Education, and Control (of Innates). The Secretary for Scotland; whose chief office is in Whitehall,

is over all, and there is a Parliamentary Secretary. Both of these are members of the Board, the Secretary for Scotland being President, and one of the Edinburgh members Vice-President. The Board has a staff of medical officers and of referees for insurance work. Under the Public Health (Scotland) Act, 1897, no one can be appointed as medical officer of health for any area, burghal or rural, however small, unless he possesses a diploma in public health. One result is that small burghs often appoint the county M.O.H. as their officer. No medical officer or sanitary inspector can be removed from office except with the sanction of the Board of Health. A "proper" salary must be paid, and it is incompetent for the local authority to bring about a resignation by indirect means, such as reducing a salary, or attaching conditions to the appointment. The Act says nothing about superannuation, and specifies no retiring age. The appointment, however, is not *ad vitam aut culpam*. Most counties in Scotland are smaller than in England, and the county medical officer is also district medical officer, being therefore both administrative and executive in function.

THE SCHOOL MEDICAL SERVICE.

School medical officers are appointed by local education authorities under schemes of medical inspection of school children which must be approved by the Board of Education. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard the education of such children, and to inform their parents of its existence. But practically their duties vary considerably in different areas. This is because most approved schemes of inspection include systems of work which aim at facilitating the task of parents in obtaining for their children the necessary treatment, at checking the results of the latter, and at keeping each defective child under skilled observation both at home and at school until it has passed altogether out of the education authority's hands. The general object of all schemes alike is to make the inspection imposed by law of benefit not merely to the individual child but to the community at large, by preventing conditions which lead to the existence of a large proportion of inefficient citizens among the adult population. The work is so far related to that of a medical officer that in most areas the senior school medical officer, at both appointments, his work, when necessary, being complemented by that of whole- or part-time assistants. Whole-time assistants are commonly paid salaries commencing at a minimum of £500 a year or less, the chief attraction of the posts being that they may lead on to appointment as medical officer of health, but we fear that not many actually do reach that position. Yet it is desirable for a prospective whole-time school medical officer to obtain a diploma in public health. In some counties and county boroughs it is now the practice for the officer to undertake certain minor ameliorative work, notably prescription of glasses when necessary, the removal of adenoids, and treatment in connexion with certain diseases of the skin. The added interest thus given to the work appears to make for increased efficiency and also enhances the value of the post. Otherwise the monotony of filling up record cards in the absence of any duty of treatment is apt to become intolerable, and if no public health functions belong to the post it gives little chance of developing into a health officership.

TUBERCULOSIS OFFICERS.

Before sanatorium benefit was transferred to the public health authorities the prescribed duties of tuberculosis officers were to act as advisers to Insurance Committees in connexion with the operation of the National Insurance Act and to take charge of the work of the tuberculosis dispensary, which is the main unit of the Departmental Committee's scheme. A tuberculosis officer is a whole-time officer, who should have special training in tuberculosis work, and be of suitable age and attainments to command general confidence. At present the number of appointments is small, and the salary generally attached to them is about £500 a year with an occasional bonus addition. In many instances they are now appointed on the staff of the medical officer of health, so that the work of prevention and cure of tuberculosis may be made part of the general health work of the Municipal Council.

VENEREAL DISEASE MEDICAL OFFICERS.

Schemes for the diagnosis and treatment of venereal disease are administered by county councils and county borough authorities have appointed

whole-time medical officers at a salary of £500 to £700 per annum. In some cases the officer is on the staff of the medical officer of health and in others he is an independent official. Specialized practical experience in the treatment of venereal disease is essential, and it is an advantage if such experience has been obtained in the navy or army. His duties usually include not only the diagnosis and treatment of cases of venereal disease at one or more central clinics, but also the instruction and supervision of the treatment by general practitioners attached to local clinics.

DIPLOMAS IN PUBLIC HEALTH.

New rules for study and examination for these diplomas come into force on January 1st, 1924, but it will be convenient in the first place to state the present position. Most of the universities and licensing corporations now grant diplomas in public health to candidates who pass the examinations imposed by them. Since all such tests must conform to the requirements of the General Medical Council, there is considerable similarity in their nature, though they differ not a little in their reputed difficulty. All of them aim at excluding any candidate who does not appear to have a thorough knowledge of his work in theory and in practice, for the regulations of the General Medical Council demand that the granting of a diploma in Sanitary Science, State Medicine, or Public Health shall be proof of the "possession of a distinctly high proficiency, scientific and practical, in all the branches of study which concern the public health." The tests, in short, are supposed to constitute an honours and not a mere pass examination. As regards the special tuition required, it is now easy to obtain this in practically every centre of medical education, and at almost every medical school of any importance. It is desirable to note in this connexion that the chemical and bacteriological examinations for many of the health diplomas are so practical, and the time allowed so short, that unless a candidate—even though familiar with the duties of M.O.H.—has a considerable amount of manipulative dexterity only to be acquired by ample work in a laboratory, he would not be likely to satisfy the examiners.

The present rules of the General Medical Council remain in force until January 1st, 1924. They require that every candidate (subsequent to obtaining a registrable qualification in medicine and surgery) shall have passed through a stated curriculum in the subjects of sanitary science. This must last not less than nine calendar months, and include four months' study in a laboratory in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught, six months' practical study of the duties involved by public health administration, and attendance at least twice weekly for three months on the practice of a hospital for infectious diseases at which instruction is given in methods of administration. These rules do not apply to practitioners registered or entitled to be registered before January 1st, 1890, while that regarding six months' practical study of public health administration is waived in the case of a candidate who has himself been in charge of a sanitary district with a population of not less than 15,000 for a period of not less than three years. The study in question must be passed under the personal supervision of a medical officer possessing certain definite facilities for affording it, these being carefully described in the regulations. The period may be reduced to three months in the case of a candidate who has undergone a corresponding period of study in the public health department of a recognized medical school, or who has been resident medical officer at a hospital for infectious diseases with accommodation for 100 patients for not less than three months. The laboratory study must include at least 240 hours' work, not more than half being devoted to practical chemistry. The examinations imposed by the diploma-granting bodies must extend over not less than four days, one at least being devoted to practical work in the laboratory, and one to practical examination in, and reporting on, subjects within the duties of a medical officer of health, including those of a school medical officer.

The steps which examining bodies take to ascertain the candidate's fitness for a diploma are in all cases much the same, though the order in which the subjects are taken is not always identical. Every candidate therefore should, when he has settled what diploma or degree in State medicine he wishes to obtain, seek the schedule relating to it from the authority concerned. A certain number of the universities grant degrees in the subject as well as diplomas. The new Rules will apply after January 1st, 1924. They require that not less than two years shall elapse after

obtaining a registrable qualification before admission to the Final Examination for a public health diploma. The curriculum shall extend over not less than twelve calendar months. At least five months must be given to practical laboratory instruction in an approved institution in (a) bacteriology and parasitology, including entomology, especially in relation to diseases of man and to those transmissible to man from the lower animals (180 hours); (b) chemistry and physics in relation to public health (90 hours); and (c) meteorology and climatology (10 hours). Not less than 80 hours' instruction in an approved institution, or by approved teachers, must be given to the following subjects, the approximate hours being as bracketed: Principles of public health and sanitation (30), epidemiology and vital statistics (20), sanitary law and administration (20), sanitary construction and planning (10).

There is required three months' attendance—30 daily attendances of not less than two hours in each week—on the clinical practice of a recognized hospital for infectious diseases, with instruction in methods of administration. Six months' practical training under a medical officer of health is an important feature of the new scheme, and the time cannot be reduced by attendance on lectures as at present. Three hours on each of sixty working days are the minimum, and the instruction is to include maternity and child welfare, the services relating to school life, venereal disease and tuberculosis, industrial hygiene, and food, meat and milk inspection.

The examination will consist of two parts, each lasting for at least two days. Part I covers bacteriology, parasitology (with medical entomology), chemistry, physics, meteorology, and climatology. Part II includes hygiene and sanitation, epidemiology and infectious diseases, sanitary laws and vital statistics, and public health administration. There will be practical examinations in infectious diseases, food inspection, and inspection of premises. Neither part can be entered on until the relative courses of instruction (after registration in medicine) have been completed, and Part I must be passed before admission to Part II.

THE PUBLIC SERVICES.

THE ARMY, AIR FORCE, AND INDIAN MEDICAL SERVICES.

THE Medical Departments of the Royal Navy, of the Army, and the Indian Government normally employed between them before the war some 3,000 medical men, and vacancies in the ranks of these services were filled by offering commissions for competition once or more each year. In the abnormal circumstances arising out of the war and the period immediately following it the usual regulations for recruiting the permanent medical staff of these services were, for the most part, in abeyance. Now that a return has been made to peace establishments we publish somewhat fuller information than we have given in recent years for the guidance of those who think of applying for regular commissions in the Royal Air Force Medical Service, the Royal Army Medical Corps, and the Indian Medical Service. Further details should be sought from the respective medical departments. The usual information regarding the conditions of service, pay, and prospects in the Medical Department of the Royal Navy is omitted this year for the reasons stated at page 449.

ARMY MEDICAL SERVICE.

ENTRANCE by competitive examination into the Royal Army Medical Corps has not yet been reintroduced, the strength of the Regular Establishment being maintained by the appointment of officers serving on temporary commissions who are selected to fill vacancies as they occur. This source of supply of officers will shortly be coming to an end, when Entrance Examinations on the same lines as those laid down in the Regulations for 1912 will again be held.

The prospects of the newly qualified medical man taking up the army as a career have been much improved by changes that have come into force since the war. The rates of pay and pension are given in the subjoined tables, and it will be found that they compare favourably with those that obtained in 1914.

Pay and Allowances.

	At Home.		In India.
	Married. £ per annum.	Unmarried. £ per annum.	Rupees a Month.
Lieutenant	625	541	650
Captain	751	657	800
Captain after 6 years' service	763	675	900
Captain after 10 years' service	824	730	950
Major	857	718	1100
Major after 15 years' service	938	909	1250
Major after 18 years' service			1430
Lieut.-Colonel	1170	1091	1550
Lieut.-Colonel after 20 years' service	1216	1137	1650
Lieut.-Colonel after 25 years' service	1252	1183	
Colonel	1489	1422	1850
Major-General	2163	2091	"According to appointment."

At Home.—An officer under the rank of lieutenant-colonel holding an appointment as specialist receives 2s. 6d. or 5s. a day (according to subject or group of subjects). An officer in charge of a hospital receives on charge pay, the daily amounts being: in excess of 50 beds, 2s. 6d.; in excess of 150, 5s.; in excess of 300, 7s. 6d.; in excess of 500, 10s. An officer in charge of a medical or surgical division of a general hospital with not less than 300 beds receives half these rates. Professors at the Royal Army Medical College receive £200, and assistant professors £80 a year, in addition to pay and allowance of their rank.

In India.—The specialist pay is 60 rupees a month; charge pay is from 60 to 240 rupees a month, according to the size of hospital.

Retirement.

A lieutenant-general or major-general must retire on attaining the age of 60 years, a colonel at 57, and other officers at 55. A major superseded for promotion retires on the completion of twenty-five years' service, or, if he fails to qualify for promotion, on the completion of twenty years' service. A captain who fails to pass the examination for promotion to major on a second trial must retire at once with any gratuity for which he may be eligible, or, if not, on completing five years' service. A lieutenant who does not qualify for promotion within three and a half years is required to resign. A candidate who has been specially employed in consequence of a national emergency will be allowed to reckon such service towards retired pay and gratuity. The maximum rates of retired pay are as follows:

Captain and subaltern	£300
Major	£450
Lieutenant-colonel	£630
Colonel	£800
Major-General	£1,000
Lieutenant-General	£1,200

Voluntary retirement on retired pay is not allowed until after twenty years' service. Earlier retirement or gratuity is allowed as follows:

Major or captain:	Gratuity.
After 21 years' commissioned service	£1,000.
" 3 years' service in the rank of major	£1,800
" 6 years' service in the rank of major	£2,500

Seconded Service.

An officer may be permitted to accept employment in the Foreign or Colonial Offices; when so seconded he is not eligible for pay or allowances from army funds, but his service continues to reckon towards promotion and, under certain conditions, towards increase of pay, pension, or gratuity. Among the capacities in which R.A.M.C. officers may be employed are:

- (1) The medical service of the Egyptian army.
- (2) The sanitary service of the Egyptian Government.
- (3) The medical services of the various foreign and colonial Governments.

Service on the West Coast of Africa.

Officers for service in West Africa are usually taken from a list of volunteers for such service. An officer at present receives, while actually serving in West Africa (which service may include ordinary leave not exceeding sixty-one days in a year, and any time spent at Madeira or the Canary Islands on sick leave), additional pay at the following daily rates: lieutenant-colonel 12s., major 9s., captain 7s. 6d., lieutenant 6s.

King's Honorary Physicians and Honorary Surgeons.

Six of the most meritorious officers of the Army Medical Service on the active list may be appointed honorary physicians to His Majesty the King, and six honorary surgeons may be similarly appointed. On appointment as an honorary physician or honorary surgeon an officer under the rank of Colonel in the Army Medical Service may be promoted to the brevet rank of colonel. The appointment of honorary

physician or honorary surgeon is relinquished on retirement. Lieutenant-colonel so appointed receives pay at the rate laid down for a colonel of the Army Medical Service.

The professional work of the corps has received a great impetus through the Directorates of Hygiene and Pathology. Specially selected and trained officers have now been appointed as assistant and deputy assistant directors of hygiene to all commands and garrisons at home and abroad. Junior officers appointed on probation will undergo a course of instruction in hygiene on entering the service, at the army school of hygiene, where lectures and demonstrations are given on the methods of sanitation, including entomology, applicable to the various climates and countries, special attention being paid to tropical hygiene.

The Directorate of Pathology offers many attractions to those officers who are desirous of taking up the scientific side of medicine. Officers who show aptitude in this direction are encouraged to continue their scientific studies during the whole course of their service. As junior officers the posts of clinical pathologists to hospitals at home and abroad are available, while, after their first tour of foreign service, they are given the opportunity of qualifying as specialists in bacteriology and pathology at the Royal Army Medical College; having so qualified they become eligible for the appointments of assistant or deputy assistant director of pathology, posts which carry with them specialist pay or temporary promotion.

Appointments to the staff of the directorate of hygiene and pathology at the War Office are open to officers who have served in these scientific branches—the senior posts carrying the rank of colonel, colonel-commandant, or major-general as the case may be. All such staff appointments, either at the War Office or in commands at home, have a fixed tenure of three or four years should the exigencies of the service permit.

Arrangements have been made for the appointment of consultants in both medicine and surgery, and the ranks of colonel and major-general are now open to such officers. This will encourage officers of outstanding ability in these subjects to continue to devote their attention to medicine and surgery, in which previously there were no openings for officers above the seniority of lieutenant-colonel.

The question of specialists has also undergone review and a great improvement in the method of training and selection has been effected. Captains undergo a six months' course at the Royal Army Medical College for promotion to major in the subjects of hygiene and pathology, together with general medicine and surgery. Of those officers who pass the Combined Examination in these subjects, the first 50 per cent. are now eligible to take out a further six months' specialist training, provided that they can prove to have had past experience in a particular subject and to have shown special aptitude for that subject. Results so far achieved by this system have, we are informed, been most encouraging. The training is undertaken by selected teachers of the various London general hospitals, as well as the army professors at the college.

It is recognized that, apart from purely professional work, it is most important that officers should receive administrative training, and the inclusion of officers of the Royal Army Medical Corps in the classes that undergo courses at the recently instituted School of Army Administration at Chislehurst will be of great advantage to the Medical Service. Many appointments of an administrative character are open to officers who show zeal and capacity for this side of the army medical officer's duties.

ROYAL AIR FORCE MEDICAL SERVICE.

The Royal Air Force Medical Service offers a career for medical men which should prove both attractive and interesting. The rates of pay and allowances are good, and a new field of scientific interest is opened up by the manifold problems which the circumstances of aviation produce. The physical and mental fitness for and reaction to the varied conditions under which the flying personnel perform their functions provide much scope for research.

As promotion to the higher ranks of the service is to be entirely by selection, and as a certain proportion of the higher ranks will be reserved for purely scientific as opposed to administrative appointments, it will be seen that there are

excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop a talent for administration.

Commissions.

The establishment will consist partly of permanent and partly of short service officers.

Short service officers will be admitted by direct entry for a period of two years, which may be extended to four years at the discretion of the Air Council on recommendation of the Director of Medical Services. Those who are not selected for permanent commissions will pass into the Royal Air Force Medical Reserve at the expiration of their period of service on the active list, and will then receive the gratuity to which their service entitles them. Short service officers who are approved for permanent commissions, but for whom there are no vacancies in the Royal Air Force Medical Service, may under certain conditions transfer to the Royal Army Medical Corps, counting their time served in the Royal Air Force towards increments of pay and retired pay in the Royal Army Medical Corps.

Officers who have been selected for permanent commissions will be granted leave for a period not exceeding nine months for post-graduate study in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such leave will be granted during the first six years of permanent service, and during such leave officers will remain on full pay and allowances.

New entrants into the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical), and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will be promoted to the rank of Squadron Leader after ten years' total service. Accelerated promotion may be carried out, in a limited number of cases, of officers who show exceptional ability after completion of eight years' service. Promotion to the rank of Wing Commander will be by selection at any time after sixteen years' total service, and to that of Group Captain by selection at any time after twenty-two years' service.

There will be no competitive examination on entry; candidates must be under 28 years of age; be nominated by the Dean of a recognized medical school or teaching hospital; and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce:

1. Birth certificate.
2. Medical registration certificate.
3. A declaration containing the following information:
 - (a) Age and place of birth.
 - (b) That he is of pure European descent and the son of a subject of the British Empire.
 - (c) That he labours under no constitutional or mental disease or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate in peace or war.
(All candidates will be required to pass a medical examination as to their physical fitness before acceptance, to ensure that they fulfil the standard laid down in this declaration.)
 - (d) That he is ready to engage for general service at home or abroad as required.
 - (e) The qualifications he is possessed of and what medical or other appointments he has held (if any).
 - (f) That he is willing to fly whenever called upon to do so, and to qualify in such aviation test as may be required.

If the applicant is in possession of a certificate of training in an Officers' Training Corps this should be submitted.

An applicant who at the time of application holds or is about to hold a resident appointment in a recognized civil hospital may be seconded for the period, not exceeding one year, during which he holds such appointment. Whilst seconded he will not receive pay from Air Council funds, but his seniority will count from the day on which he is seconded to the civil hospital.

Uniform and Equipment.

Medical officers will be required to provide themselves with the uniform of their rank, and with the distinguishing badges of the Royal Air Force Medical Service. They will be required to provide themselves with service dress and mess dress. The provision of full dress is entirely optional.

Officers will be granted to officers if they have previous service. If they have had previous service in the Navy, the Army, or the Royal Marines, but not in the Royal Air Force, they will receive an outfit allowance of £25.

Rates of Pay.

The rates of pay in the Royal Air Force Medical Service are set out in the following tables:

Rank and Years of Service.		Rate per Diem.	
Flying Officer:		s. d.	
On joining	...	24	0
Flight Lieutenant:		s. d.	
On promotion	...	26	0
After 2 years in the substantive rank	...	28	0
4 years	...	30	0
Squadron Leader:		s. d.	
On promotion	...	34	0
After 2 years in the substantive rank	...	36	0
4 years	...	38	0
6 years	...	42	0
Wing Commander:		s. d.	
On promotion	...	46	0
After 2 years in the substantive rank	...	50	0
4 years	...	52	0
6 years	...	54	0
Group Captain:		s. d.	
On promotion	...	60	0
After 2 years in the substantive rank	...	64	0
4 years	...	68	0

Rates of Pay in India.

	Rs. per Mensem.
Flying Officer	650
Flight Lieutenant	750
After 2 years as such	850
4 years	900
Squadron Leader	1,650
After 2 years as such	1,100
4 years	1,150
6 years	1,250
Principal Medical Officer	1,950

The scale of Retired Pay for Group Captains and lower ranks is given in the following table:

Age.	Service Counting for Retired Pay.	Rate of Retired Pay.	Addition for each Extra Year of Service.*	Reduction for each Deficient Year of Service.*
55	21	750	22	15
54	24	765	22	15
53	21	742	22	15
52	23	720	22	15
51	22	697	22	15
50	22	675	15	15
49	21	637	15	15
48	21	603	15	15
47	21	562	15	15
46	20	525	15	15
45	19	487	15	15
44	19	450	15	15
43	18	412	15	15
42	18	375	15	15
41	17	337	15	15
40	17	300	15	15

* Limited to five years.

There will be a minimum qualifying period for retired pay of twenty years.

Gratuities.

Short-service officers will receive gratuities at the rate of £100 for each of the first two completed years of service, and at the rate of £150 for the third and fourth completed year. (If granted permanent commissions these gratuities will not be payable, but the period of service under the short-service commission will count for retired pay.)

Medical officers hold-
eration of the Air Con
after ten years' servi
years with a gratuity

may, at the dis-
from the service
or after sixteen
J.

Allowances.

The usual allowances will be payable to medical officers under the same conditions as to officers of other branches of the Royal Air Force.

INDIAN MEDICAL SERVICE.

For some years before the war the pay and conditions of service in the I.M.S. were unfavourable. The pay, furlough pay, and pensions were inadequate; leave was difficult to obtain; the status of administrative medical officers was unsatisfactory. The new terms offered by the Secretary of State for India were announced in 1920, and the Representative Body of the British Medical Association, finding that they satisfied the Association's demands, resolved unanimously to accept them.

Under the reform scheme now being brought into effect medicine is a transferred subject—that is to say, it will in

future be under the control of the Provincial Governments and legislatures. In the present state of transition the position which the Indian Medical Service will in future occupy is not well defined, and it seems unnecessary, therefore, to reproduce here in full the conditions of service. Full details and particulars can, however, be obtained from the Secretary, Military Department, India Office, Whitehall, London, S.W.1.

It is, we understand, possible that a scheme of appointments to the Indian Medical Service for a limited period may be promulgated before long.

THE ROYAL NAVAL MEDICAL SERVICE.

A WARNING.

In January, 1920, as a consequence of the report of the Jorram-Halsey Committee, new regulations for retirement of officers came into force in the Royal Navy, and new rates of pay were laid down. The new regulations inflicted a great injustice upon a considerable number of surgeon commanders who were nearing, or had passed, the new retiring age. The grievance arose under two heads—age of retirement and rate of pension—and frequent remonstrances were addressed to the Admiralty by the British Medical Association. An account of the matter will be found in a leading article in the BRITISH MEDICAL JOURNAL of July 8th, 1922 (p. 52).

The Grievance of the Senior Surgeon Commander.

Very briefly stated, these medical officers, who had entered the Service on the understanding that they would be allowed to serve until the age of 55, were compulsorily retired at 50, and their maximum pension was fixed at £600 a year, representing an increase of but 10 per cent. on the former retired pay of their rank; it should be particularly observed that officers of other branches got increases of pension varying from 25 to 100 per cent. In reply to representations by the British Medical Association the Admiralty admitted the grievance, but declined to remedy it, on the ground that legislation for individual cases of hardship was not practicable. So far from the matter affecting two or three individuals alone, we would point out that the new regulations were unjust to some 80 or more surgeon commanders approaching the new age of retirement. The Council of the Association at length warned the Admiralty that if the question could not be settled satisfactorily it would be obliged to place the facts before the profession; and to advise young medical men that if they entered the Royal Naval Medical Service they must do so with the knowledge that, with its present policy, the Admiralty cannot be trusted to keep any engagement it may make with its medical officers.

The Moral.

The matter, as has been pointed out in these columns, is one of elementary justice. The Admiralty is responsible for the Naval Medical Service. Remembering the treatment of senior surgeon commanders, the Association's advice to medical students and young practitioners is to consider seriously the disadvantages to which they are liable if they place their careers in the hands of the Admiralty.

The Representative Body of the Association during its Annual Meeting at Glasgow this summer heard an account of this grievance from the Chairman of the Naval and Military Committee, and the subsequent debate was reported in the SUPPLEMENT of August 5th at page 76. It will be seen from this that the Council's warning to recently qualified medical practitioners was fully approved, and indeed the feeling of the Representative Body was in favour of even stronger action. Speaker after speaker reprobated the treatment of naval medical officers by the Admiralty, and condemned the breaking of the definite undertaking given to senior surgeon commanders. A former Chairman of the Organization Committee, recalling the action taken by the British Medical Association some years ago in connexion with the Army Medical Service, made the significant remark that it was the failure to procure candidates for that service which brought the War Office to reason. The outcome of the debate was an emphatic endorsement by the Representative Body of the policy put forward by the Council.

It may be hoped that long before next year's Educational Number appears the Admiralty will have seen the wisdom of putting itself right in the eyes of the medical profession. If

this is done, we shall be able to include once again a statement of the conditions under which commissions are granted in the Medical Department of the Royal Navy, and in other ways give encouragement to prospective candidates.

PRISON MEDICAL SERVICE.

CANDIDATES for the medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. The Chairman of the Board is M. L. Waller, Esq., C.B. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W.1.

In the smaller prisons the medical officer is usually a local practitioner, but in the larger the members of the medical staff are required to devote their whole time to the service. In the case of those required to give their whole time to the service the appointment in the first instance is to the post of medical officer Class II, and from the seniors of this rank the medical officers Class I are selected as vacancies occur.

The pay of the whole-time prison medical staff is: Medical officer Class II, £300, rising by annual increments of £15 to £500; medical officer Class I, £550, rising by annual increments of £20 to £700. Unfurnished quarters are provided, or an allowance in lieu is made. The Civil Service bonus is paid on the salary. There are 15 medical officers Class II, 10 medical officers Class I, and 33 part-time medical officers.

The number of vacancies is never large, and promotion is slow. Although there has recently been some improvement in the scale of pay, the remuneration both of whole-time and part-time prison medical officers is unsatisfactory.

MEDICAL PRACTICE IN BRITISH DOMINIONS AND FOREIGN COUNTRIES.

MEDICAL Acts have now been passed in almost all places forming part of the British Empire beyond the seas, and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are always admissible merely on payment of a registration fee, providing they produce evidence that they are of good repute and are either registered or eligible for registration in the United Kingdom, as the local requirement may be. The only exception to this statement that need be made relates to the Dominion of Canada. Each of its provinces acts in medical matters as an independent State. The result has been that reciprocity of practice has been established between this country and all the Provinces of Canada except British Columbia, where certain obstacles still remain to be overcome. We would advise any medical man proposing to practise in Canada first to communicate with the Provincial Registrar, stating what degrees or diplomas he holds, and asking for information as to the precise steps he must take in order to obtain admission to the Provincial Register.

Italy, Japan, Egypt, and (within certain limitations) the Principality of Monaco, are the only foreign States which accord a right to practise in virtue of British degrees and diplomas, though the authorities of Holland and Greece sometimes exempt British practitioners from portions of the examinations imposed on ordinary candidates for registration. In all other Continental countries a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. The same observation applies to all foreign States in the South American continent. Each of the United States of North America has its own laws and regulations governing medical practice; some of the States admit any holder of a degree or diploma to their Register, but the majority require a candidate for registration to submit to an examination.

A pamphlet showing the conditions under which medical and dental practitioners legally qualified in their own country may practise abroad can be obtained from the office of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, price 2s. 6d., or 2s. 9d. post free in the United Kingdom. Practitioners who think of going abroad to practise will find therein much useful information, including the name of the official in each country to whom requests for further particulars should be addressed. The last edition as published in January, 1921.

MEDICAL APPOINTMENTS UNDER THE COLONIAL OFFICE.

APPOINTMENTS to the Medical Services of the Colonies and Protectorates under the administrative control of the Colonial Office are made by the Secretary of State for the Colonies. Such appointments are to the service of a given colony or colonies, for there is no unified service directly administered from the Colonial Office. It follows that conditions of service and superannuation are in the main determined by the economic resources and general public health policy of the individual colony and its local government, and vary almost as widely as do conditions of climate. Moreover, the extent of the control exercised by the Colonial Office varies according to the constitutional status of the particular colony, and the detailed information available centrally is not always complete. The intending candidate, therefore, should make comprehensive inquiries as to local conditions before applying for an appointment, and will do well to supplement official information by reference to the central office of the British Medical Association, where reports obtained from time to time from the local Branches are available. This is the more necessary because facilities for transfer from the service of one colony or group of colonies to that of another are as yet practically non-existent, except in connexion with a few specialist and senior appointments; this sets strict limits upon the opportunities for promotion.

The bulk of the medical appointments made by the Secretary of State in this country are to the services in the East and West African Colonies and Protectorates, the Straits Settlements and Malay States, the East Indies, and Fiji and the Western Pacific. In general, candidates for such appointments must be between the ages of 23 and 35; and whilst these limits are not for the moment absolute, an officer over 35 years of age on first appointment may be required to serve on a temporary and non-pensionable footing; regular appointments are, subject to a varying period of probation, for the most part permanent and pensionable. There is no entrance examination, but practitioners selected for appointment must obtain a certificate of physical fitness from one of the Medical Advisers of the Colonial Office. In the case of the West African Medical Staff and the East African Services successful candidates are required to undergo an approved course of instruction in tropical medicine.

Colonial Service: The Outlook.

Whilst colonial service offers undoubted attractions to some practitioners it also presents very definite disadvantages, and not the least of these is, at the present time, uncertainty as to the future. Before the war conditions in several of the services gave rise to considerable anxiety; the greatly enhanced cost of living during the war resulted in certain more or less inadequate temporary advances in remuneration, but consideration of the radical reforms required was postponed until the succeeding period of reconstruction. In 1919 a Departmental Committee under the Chairmanship of Sir Walter Egerlon was appointed to consider the position of the Services generally, the means of securing contentment within them, and the maintenance and increase of the supply of candidates. The Committee found that the ideal to be aimed at was the creation of a unified Colonial Service, recruited by competitive examination and represented on the staff of the Colonial Office by a Medical Director-General. As an immediately practicable step in this direction it recommended the assimilation of the medical services in neighbouring colonies, and more especially those in the East African and Malayan groups. A permanent increase of salaries with a general minimum of not less than £600 a year on first appointment was recommended; the necessity for study leave was recognized, as was the need for the development of facilities for research; an increase in the number of specialist appointments and adequate provision for promotion by transfer from the service of one colony or group to that of another were other points emphasized.

Progress along the lines laid down by the Committee, which correspond broadly to the policy adopted by the British Medical Association, has undoubtedly been made since the report of the Committee was issued. With the exception of the West Indian Services, the Fiji and Pacific Colonies, and a few of the smaller dependencies which each offer only one or two medical appointments, the adoption of the £600 minimum or its equivalent in local coinage has been achieved. The commencing pay in the West African Medical Staff is £650 a year. For all practical purposes the Services

in the Malay Peninsula have been unified, and some steps have been taken towards the assimilation of the East African Services, whilst there has been an appreciable increase in the number of specialist appointments and the facilities for research. The Services, however, remain understaffed. Opportunities for promotion, failing means of transfer from one service to another without loss of pension, must remain inadequate. Certain services, notably those in the West Indies and Fiji, have not yet secured that measure of reform essential to a minimal standard of efficiency, and it seems clear that the final unification of the East African Medical Services under conditions approximating to those of the West African Medical Staff will be indefinitely postponed.

Moreover, the acute economic depression of the last two years has affected many of the colonies with almost crushing severity, and has in some cases brought about the indefinite postponement of projected reform, and in others practically neutralized advances in remuneration that were at one time thought to be permanent, besides imposing disastrous restrictions on the public health programme in many places. Nor do economic difficulties, radical though they are, stand alone. The constitutional status of the colonies is under review. Schemes for regrouping and for the concession of greater local autonomy may be temporarily delayed pending economic recovery, but it is not unreasonable to suppose that until such questions are settled there can be little progress towards the unification of the Colonial Medical Service. Their adoption, on the other hand, may entail the formulation of a new solution for the admitted difficulties. The future is therefore extremely uncertain, and in spite of the definite advance recorded above it is impossible at present to modify the warning that prospective candidates should consider carefully whether they may not be well advised to look elsewhere for a career. Caution is especially necessary in connexion with appointments in the West Indies and Fiji. The position as regards the West Indies was fully discussed in these columns in connexion with the Report of the Under-Secretary of State for the Colonies on his recent tour in the West Indies (*BRITISH MEDICAL JOURNAL*, July 15th, 1922, p. 99, and SUPPLEMENT, p. 22). The position in Fiji is at the moment engaging the attention of the Dominions Committee of the British Medical Association in connexion with representations received from the Fiji Branch.

The condition of the Colonial Medical Services has for some time been a matter of the gravest concern to the Association, which gave evidence on the subject before the Egerton Committee, and has been in constant communication with the Colonial Office on matters touching their welfare since August, 1921. During this period the Association has, in effect, been recognized as the mouthpiece of the Services, and has received copies of all official documents primarily affecting medical officers, and also the gazettes of the various local governments. It has therefore been possible to supplement the activities of the Overseas Branches by the exercise centrally of unceasing vigilance over all tendencies likely to affect the development of the Colonial Services. It cannot be too strongly emphasized, however, that present conditions render immediate advance impracticable.

Official Sources of Information.

All inquiries in connexion with colonial medical appointments made by the Secretary of State for the Colonies should be addressed to the Assistant Private Secretary (Appointments), Colonial Office, Downing Street, S.W.1. Any vacancies occurring in Iraq, Palestine, and Aden are recruited through the Colonial Office, and information can be obtained at the same address. Vacancies also occur, though at rare intervals, in the Sudan, and inquiries as to these should be addressed direct to the Civil Secretary, Sudan Government, Khartoum. Inquiries about any medical appointments made by the Egyptian Government should be addressed to the Director-General, Public Health Department, Cairo.

Information as to medical appointments in the self-governing Dominions and their dependencies can be obtained on application to the High Commissioners or Agents-General for the Dominions. Intending applicants are also recommended to consult the Colonial Office List and the Professional Handbook (price 6d.) issued by the Overseas Settlement Office, 6, St. James's Square, S.W.1.

There remain a number of medical appointments made by mining companies and other commercial undertakings in various parts of the tropics. Much caution should be exercised in accepting such posts, and the form of contract should

be subjected to very careful scrutiny. Advice in this connexion should always be sought at the central office of the British Medical Association.

MEDICAL MISSIONARIES.

To medical men suitably endowed the mission field offers opportunities for interesting work. There are now 415 medical practitioners holding British degrees or diplomas employed in different parts of the world by missionary societies, and the latter seem to stand in constant need of men and women to fill vacancies as they occur, and also to enable them to take advantage of fresh openings. Since the conclusion of the war there has been a large number of such vacancies, as most of the mission hospitals are working with depleted staffs. Further, the development of native medical schools as training institutions in connexion with some of the larger mission hospitals affords excellent scope for most useful work to medical men who are qualified to teach. It is not usually expected or desired that a medical missionary should take a position such as would otherwise be occupied by an ordained clergyman or minister. But it is essential that he should be prepared to take his share of definite missionary work in any hospital in which he may be placed. As for scientific and other qualifications for the work, a medical missionary, in addition to being physically capable of sustaining what may prove to be a trying life, should be a thoroughly well trained physician and surgeon. It is very desirable that he should have held a resident appointment at a general hospital and have a good knowledge more particularly of practical surgery, tropical medicine, and the treatment of eye diseases. Societies from whom useful information can be obtained are the London Medical Missionary Association, 49, Highbury New Park, N.5; the Edinburgh Medical Missionary Association, 56, George Square, Edinburgh; the Church Missionary Society (Medical Mission Department), Salisbury Square, London, E.C.4; the Society for Promoting Christian Knowledge, Northumberland Avenue, W.C.2; and the Medical Missions Department of the Society for the Propagation of the Gospel in Foreign Parts, 15, Telford Street, Westminster, S.W.1.

Dental Surgery.

UNTIL the passing of the Dentists Act, 1921, the profession of dentistry in this country was regulated by enactments very closely similar to those relating to the practice of medicine—that is to say, there was no direct prohibition of the act of practice; and the Dentists Act gave the same degree of protection to legally qualified and registered dentists as was accorded to registered medical practitioners—namely, the reservation of the use of certain titles. The Dentists Act, 1878, provided (1) that no person should take or use the name or title of "dentist" (either alone or in combination with any other word or words) or of "dental practitioner," or any other name, title, or description expressed in words or by letters implying that he was specially qualified to practise dentistry, unless he was registered, under a penalty of £20; and (2) that an unregistered person could not recover any fee or charge in respect of any dental operation, attendance, or advice. But, in the case of the practice of medicine by unqualified and unregistered persons, certain deterrent factors came into play—such as the inability to give a death certificate—and these did not operate to the same extent in the case of dentistry; hence, unqualified practice has been far more prevalent in dentistry than in medicine, and this increased after a decision of the House of Lords placing a narrow interpretation upon the words "specially qualified to practise dentistry," by defining the word "qualified" as not referring to competence but to the possession of a recognized diploma.

The Dentists Act, 1921.

This unsatisfactory position has now been remedied by the passing into law of the Dentists Act, 1921; its provisions are based largely on the recommendations of a Departmental Committee appointed in 1917 by the Privy Council "to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not

qualified under the Dentists Act." After November 30th, 1922, no person may practise or hold himself out, whether directly or by implication, as practising or as being prepared to practise dentistry unless he is on the *Dentists Register* provided for by the Dentists Act, 1878. The practice of dentistry is defined as including "the performance of any such operation and the giving of any such treatment, advice, or attendance as is usually performed or given by dentists," and the performing of any operation or the giving of any "treatment, advice, or attendance on or to any person as preparatory to or for the purpose of or in connexion with the fitting, insertion, or fixing of artificial teeth." The maximum penalty incurred by an unregistered dentist is £100 for each offence. There are, however, certain important exceptions to the requirement of registration. A registered medical practitioner may practise dentistry without being on the *Dentists Register*, and a registered pharmaceutical chemist or chemist and druggist may extract a tooth where the case is urgent and where no doctor or dentist is available, but the operation must be performed without any kind of anaesthetic; further, any person may carry out minor dental work in a public dental service under the personal supervision of a registered dentist provided it is in accordance with conditions approved by the Minister of Health after consultation with the Dental Board.

Those qualified by examination under the new Act. They must be of 18 years of age before July 28th, 1921, and they must have been practising dentistry in the British Islands, or have been admitted to membership of the Incorporated Dental Society not less than one year before the commencement of the Act. The passing of "the prescribed examination in Dentistry" within two years of the commencement of the Act will be considered as equivalent to practising for five years, and a registered pharmaceutical chemist or a chemist and druggist who immediately before the commencement of the Act had a substantial practice as a dentist, including all dental operations, will also be treated as though he had practised for five years. A dental mechanic who for the five years has been carrying on his work as such may be registered provided within ten years of the commencement of the Act he passes the prescribed examination.

Dentistry may be carried on by a corporate body provided the majority of the directors and all the operating staff are registered dentists, and that no other business than dentistry or only some business ancillary to dentistry is carried on by the company. Companies carrying on the business of dentistry at the present time are permitted to continue to do so with certain restrictions, provided that the names of the directors have been entered in a list kept by the registrar for the purpose. Every director or manager of a company convicted of an offence under the Act will be held to be guilty of the offence unless he proves that the offence was committed without his knowledge, and the court may, in addition to a fine, order that the name of any director convicted shall be removed from the list of directors aforesaid.

THE DENTAL BOARD.

The Dental Board of the United Kingdom has been established for the purpose of administering the new Act. The first members hold office for three years, subsequent members for five years. The Privy Council has appointed the chairman and two members, the latter being dentists not registered under the principal Act. The General Medical Council has appointed three members who must be members of the Branch Council for England, Scotland, and Ireland respectively. Three persons who are neither medical practitioners nor dentists represent England, Scotland, and Ireland, and four registered and qualified dentists have been appointed—two by the Minister of Health, one by the Scottish Board of Health, and one by the Lord Lieutenant of Ireland. At the end of three years the two members being dentists not registered under the principal Act, and the four members registered under that Act appointed by the Minister of Health (two), the Scottish Board of Health, and the Lord Lieutenant of Ireland, will be replaced by four members who will be elected by qualified dentists practising in the three countries and two by registered dentists who are not qualified.

On the establishment of the Dental Board, which began its first session on December 7th, 1921, certain powers and duties of the General Medical Council were transferred to it, including the duty of erasing from the *Dentists Register* any entry which has been incorrectly or fraudulently made. An inquiry into the case of a person alleged to be liable to have his name erased from the *Register* will be made by the Board, which will report its finding to the General Medical Council, the order directing the erasure being made, as at present, by the Council. A name erased from the *Register* can only be

restored by the Council upon a report made by the Board. An appeal to the High Court may be made by any person aggrieved either by refusal of the Board to register his name or by the removal of his name from the *Register*. The first registrar was appointed by the General Medical Council with the approval of the Privy Council, and he holds office for three years; subsequent appointments will be made by the Board. The administrative expenses of the Board are to be defrayed from the registration fees and annual retention fees, but any surplus may be allocated to purposes connected with dental education and research or to any public purpose connected with dentistry. The office of the Dental Board is at 44, Hallam Street, London, W.1.

DENTAL EDUCATION AND EXAMINATION.

The preliminary examination in Arts is the same for medical and dental students, and the early stages of their education embrace much the same subjects; and, as the dental student is required to obtain a knowledge of the broad principles of medicine and surgery, it is necessary for him to pursue some portion of his studies at a medical school as well as at a special dental school, the latter not undertaking the teaching of these subjects. Registration as a dental student is not in all cases compulsory, though it is to be advised as convenient as affording proof of the commencement of professional education, and it is required by most of the licensing bodies, all of whom insist upon a curriculum covering four academic years.

Qualifying licences are granted by the Royal Colleges of Surgeons of England and of Edinburgh and of Ireland; by the Royal Faculty of Physicians and Surgeons, Glasgow; and by certain of the universities in the United Kingdom.

Recognized dental schools are numerous. In London there are those connected with the Royal Dental Hospital, Leicester Square; the National Dental Hospital (now the University College Hospital Dental School), Great Portland Street; Guy's Hospital; and the London Hospital. In the provinces there are the Birmingham Dental Hospital; the Royal Infirmary and the General Hospital, Bristol; the Dental Hospital and the Public Dispensary, Leeds; the Dental Hospital, Liverpool; the Dental Hospital, Manchester; the Dental Hospital, Newcastle-on-Tyne; the Royal Hospital, Sheffield; in Scotland there are the Dental Hospital, Dundee; the Dental Hospital, Edinburgh; and the Dental Hospital, Glasgow; and in Ireland the Dental Hospital of Ireland and the Royal College of Surgeons in Ireland.

Study may also be commenced in the dental department of any university of the United Kingdom.

There are considerable variations in the order in which the different licensing bodies require the various subjects of the curriculum to be taken up, and every prospective dental student should study not only the regulations of the General Medical Council but also those of the body whose licence he hopes to obtain. This is the more important as in the case of some licensing bodies changes in the curriculum, with the view of making it more closely adapted to the needs of the practising dentist, have either already been made or are in contemplation.

Recommendations of the General Medical Council.

The Dentists Act still leaves to the General Medical Council the duty of controlling the course of study and examinations required for dental qualifications.

The following recommendations as to the course of study and examinations to be required of candidates for degrees or licences in dentistry or dental surgery were adopted by the Council on May 27th, 1922. They are intended to come into operation on January 1st, 1923.

Preliminary Examination and Registration.

1. That every dental student shall, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for medical students.
2. That before registration in the *Dental Students Register* every applicant shall be required to have passed, in addition to the examination in general education, which shall be the same as that required for medical students, an examination in Elementary Physics and Elementary Chemistry, conducted or recognized by one of the licensing bodies, which shall also be the same as that required for medical students.
3. That before registration as a dental student every applicant shall produce evidence that he has attained the age of 17 years.

Professional Study.

4. That every candidate for a degree or licence in dentistry or dental surgery shall be required before admission to the final or qualifying examination to produce certificates showing:

- (i) That he is at least 21 years of age.
- (ii) That he has been registered as a dental student.
- (iii) That he has, subsequently to the date of registration as a

¹ See the Registrar's Memorandum, printed in the article on the General Medical Council at p. 415.

dental student, been engaged in professional study for at least four years, of which three years at least shall be spent at a school or schools recognized for professional study by one of the licensing bodies.

(iv) That, subsequently to the date of registration as a dental student, he has attended at a recognized medical school courses of instruction, which shall be the same as those required for medical students, in the following subjects: (a) Chemistry, and (b) Physics, in their application to Medicine; (c) Elementary Biology.¹ That he has attended at a recognized medical school courses of instruction in the following subjects: (d) Human Anatomy (with dissections and demonstrations) for three academic terms; (e) Physiology (with laboratory instruction, including practical Histology) for two academic terms; (f) General Pathology (including Bacteriology) for two academic terms; (g) Medicine for two academic terms; (h) Surgery for two academic terms; (i) the practice of a recognized general hospital or hospitals of not less than eighty beds, with certified instruction in Clinical Medicine and Clinical Surgery, for four academic terms.²

(v) That he has attended at a recognized dental school courses of instruction in the following special subjects: (a) Dental Anatomy and Physiology, human and comparative. The course should comprise a minimum of twenty meetings of the class. (b) Practical Dental Histology and Morbid Histology. The course should comprise a minimum of sixteen meetings of the class. (c) Dental Pathology and Surgery. The course should comprise a minimum of twenty meetings of the class. (d) Dental Materia Medica and Therapeutics. The course should comprise a minimum of sixteen meetings of the class. (e) Dental Metallurgy (with practical work and demonstrations). The course should comprise a minimum of twenty meetings of the class. (f) Dental Mechanics (with practical work and demonstrations). The course should comprise a minimum of twenty meetings and twenty demonstra-

¹ A student who has diligently attended an approved course of Elementary Biology in a secondary school or other teaching institution recognized by a licensing body may be admitted to a professional examination in elementary biology immediately after his registration as a dental student.

² The teaching in Anatomy, Physiology, Pathology, Medicine, and Surgery should take cognizance of the special needs of dental students. The certificates of teaching at general hospitals should furnish evidence of the student having acted as medical clinical clerk and surgical dresser, and of attendance in the out-patient or casualty department. A certificate of clinical instruction in venereal disease should be required.

tious. (g) A course of instruction in the use of Anaesthetics, general and local, employed in Dental Practice.³ (h) A course of instruction in Radiology as applied to Dentistry.

(vi) That he has for at least twenty-four calendar months attended, during the ordinary academic terms, the practice of a recognized dental hospital or of the recognized dental department of a general hospital.

(vii) That he has received for not less than twenty-four calendar months, or for 2,000 hours, practical instruction in dental mechanics.⁴

Professional Examinations.

5. That the examination for a degree or licence in dentistry or dental surgery shall be partly written, partly oral, and partly practical, and shall include the following subjects: (a) Chemistry, Physics, and Biology, in their bearing on Medicine and Dentistry. (b) Human Anatomy and Physiology. (c) General Pathology, including Bacteriology. (d) Medicine and Surgery. (e) Dental Anatomy and Physiology, Dental Pathology, Dental Surgery (including Orthodontics), Dental Materia Medica and Therapeutics, and Dental Mechanics and Dental Metallurgy. (f) Practical Examination in Dental Surgery. (g) Practical Examination in Dental Mechanics and Metallurgy. (h) Anaesthetics, general and local, employed in Dental Practice.

6. That the prescribed subjects of examination may be combined or distributed at the discretion of the licensing bodies, and may be taken at two or more successive stages during the course of professional study; provided that no candidates shall be admitted to any final Examination in Dental Surgery and Dental Mechanics until he shall have completed the required four years' course of study.

³ A candidate should produce a certificate of having administered on occasions.

⁴ Instruction which is taken prior to the time when a portion of the four years of professional study required. It is recommended that instruction in dental mechanics be taken at a recognized dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dentist, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school. Where in the foregoing the expression "course" is used, it is not intended that this should be read as necessarily implying a range of the

of the

The British Medical Association:

ITS AIMS, WORK, AND CONSTITUTION.

THE British Medical Association (as briefly stated at the close of our introductory article) was founded in 1832 to promote the medical and allied sciences, to maintain the honour and interests of the profession, and foster a feeling of friendship among its members. To attain these objects it holds periodical meetings for the discussion both of medical and scientific subjects, and of professional affairs; it publishes the *British Medical Journal*; it maintains a reference and lending library; it has instituted lectures, scholarships, and grants for research work; and does an immense amount of work on behalf of practitioners. The British Medical Association is the oldest, largest, and most powerful British organization devoted to the welfare of the medical profession. It owns a large freehold building, centrally situated in London, and its funds and resources are commensurate with a membership of more than 24,000.

Constitution and Administration.

The Association has Branches and Divisions throughout Great Britain and Ireland, and also in the Dominions, Colonies, and Dependencies. The Divisions are arranged territorially, and number, in all, 282. For certain purposes of administration or of scientific and clinical work, the Divisions are combined into 92 Branches. Members of Divisions elect Representatives on the Branch Councils and also a member or members of the Representative Body, which is the governing body of the Association and determines its policy.

The Council is the executive of the Association. It is elected partly by the Divisions and Branches and partly by the Representative Body, and includes representatives of the Navy, Air Force, Army, and Indian Medical Services elected by the Representative Body. The Representative Body and Council elect standing Committees to take charge of different subjects. Among these may be mentioned the Science, Medico-Political, Ethical, Hospitals, Public Health, and Naval and Military Committees. There are Committees also for the Dominions, Scotland, Ireland, and Wales; and for the

working machinery of the Association, such as the Organization, Finance, and Journal Committees. The Insurance Acts Committee, elected partly by the Association and partly by insurance practitioners, is financed by the Association.

Privileges of Members.

A member of the British Medical Association has the right—

1. To attend the annual and other general meetings of the Association and the meetings of the Division and Branch to which he or she belongs.
2. To take part by personal vote (or in some Divisions by voting paper) in the election of the representative of his or her Division in the Representative Body, and also in the election of members of the Council.
3. To receive by post the *British Medical Journal*, published weekly, which gives a full record, with commentary, of progress in clinical and scientific medicine, and of medico-political affairs throughout the British Empire.
4. To receive the help and advice of the central office in any professional difficulty.
5. To use the library as a reading room, and to borrow current medical or scientific books on payment of postage. Besides modern works and periodical medical literature—foreign as well as English—the library contains many books of historic interest.

The full benefits of the Association can only be secured by the co-operation of large numbers of the medical profession, who by their annual subscriptions provide the necessary funds. The greater the membership and the funds the more efficient and influential the organization. The Association during the past ninety years has been the direct means of benefiting every class of medical men and medical women. In asking for new members it looks not only to the older practitioners but also and especially to those recently qualified. To these a generous concession is made as regards subscription, and there is a special claim to their recognition of the work of the British Medical Association in improving the conditions under which they may hold appointments in the public services or in civil life. The Association's work for the Services is well known. It considers itself to be in

a special sense the guardian of the interests of those members of the profession who by reason of their position are precluded from taking common action. At the present time, when nearly all the Imperial services are being cut down both in numbers and in remuneration, it is ordinary prudence for every medical officer to join his professional organization.

Subscriptions and Applications for Membership.

The ordinary subscription to the British Medical Association is 3 guineas a year for members resident in the United Kingdom, but this is subject to various exceptions. Thus, newly qualified practitioners elected within two years of registration pay half this sum up to the end of the fourth year after registration; commencing on January 1st, 1923, medical officers on the active list of the R.N., R.A.F., R.A.M.C. (Regular), and I.M.S. will pay 2 guineas; concessions are made also to members (in the United Kingdom) of forty years' standing, to members of ten years' standing who have retired from practice, to medical married couples residing together, and, from January 1st, 1923, to whole-time teachers and research workers. The ordinary subscription for members living abroad is 1½ guineas, but some Branches have special local subscriptions.

All duly qualified British medical practitioners are eligible for election as members. Full particulars can be obtained on application to the Medical Secretary, British Medical Association Building, 429, Strand, London, W.C.2; the Scottish Medical Secretary, 19, Rutland Square, Edinburgh; or the Irish Medical Secretary, 16, South Frederick Street, Dublin.

British Medical Association.

OFFICES AND LIBRARY, 429, STRAND, LONDON, W.C.2.

Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.

LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded, if desired, on application to the Librarian, accompanied by 1s. for each volume for postage and packing.

VACANCIES.

BRADFORD COUNTY HOSPITAL.—House-Surgeon (male).—Salary, £200 per annum.
BIRMINGHAM EDUCATION COMMITTEE.—Part-time Aural Surgeon. Remuneration, 3 guineas per half-day.
BRISTOL EYE HOSPITAL.—House-Surgeon. Salary, £150 per annum.
BRISTOL ROYAL INFIRMARY.—Assistant Anaesthetist. Honorarium, £100 per annum.
BURNLEY COUNTY BOROUGH.—Venereal Diseases Medical Officer and Assistant to Medical Officer of Health. Salary, £85 per annum.
CAMBRIDGE MENTAL HOSPITAL, Fulbourn.—Senior Assistant Medical Officer (male). Salary, £400 per annum, rising to £500.
CARDIFF: KING EDWARD VII HOSPITAL.—House-Surgeon for Ear, Nose, and Throat Department. Salary, £150.
CUMBERLAND INFIRMARY.—Medical Officer (male), six months as Honorary Medical Officer (£175 per annum); and six months as Honorary Medical Officer (£200 per annum).

DENBY COUNTY ASYLUM.—Medical Superintendent. Salary, £1,000 per annum and emoluments.

DORCHESTER: DORSET COUNTY HOSPITAL.—House-Surgeon. Salary, £150.

EXETER: ROYAL DEVON AND EXETER HOSPITAL.—House-Physician (male). Salary at the rate of £150 per annum.

HASTINGS UNION.—Medical Officer of the Poor Law Institution Children's Homes, District Medical Officer, and Public Vaccinator. Combined salary, £450 per annum, rising to £550, with extra fees.

HEREFORD: VICTORIA EYE AND EAR HOSPITAL.—Honorary Surgeon.

IPSWICH: EAST SURREY AND IPSWICH HOSPITAL.—(1) House-Surgeon for Ear, Throat, and Nose Department. (2) House-Surgeon for general surgery. Salary in each case at the rate of £550 per annum.

KNOWLE MENTAL HOSPITAL, Fareham.—Third Assistant Medical Officer (male). Salary, £300 per annum, rising to £350.

LONDON TEMPERANCE HOSPITAL, Hampstead Road, N.W.—(1) House-Surgeon. (2) Casualty Officer. Salaries, £200 and £100 per annum respectively.

MANCHESTER CHILDREN'S HOSPITAL.—(1) Resident Medical Officer for a period of six months. Salary at the rate of £150 per annum. (2) Resident Surgical Officer. Salary, £100 per annum. (3) Assistant Medical Officer (non-resident) for Out-patients' Department. Salary £100 per annum.

MIDDLESEX HOSPITAL.—Surgical Registrar.

NORTHAMPTON: ST. ANDREW'S HOSPITAL FOR MENTAL DISEASES.—Second Assistant Medical Officer. Salary, £400 per annum, rising by £25 a year to £450.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford, E.—House-Surgeon. Salary, £150 per annum.

ROXBURGH DISTRICT MENTAL HOSPITAL, Melrose.—Assistant Medical Officer (male), unmarried. Salary at the rate of £300 per annum.

ROYAL FREE HOSPITAL, Gray's Inn Road.—(1) and (2) First and Second Assistants to the Medical Officer in charge of the V.D. (Female) Department. Salaries, £200 and £100 per annum respectively. (3) Medical Registrar. Salary, £100.

ROYAL HALIFAX INFIRMARY.—Second and Third House-Surgeons (male, unmarried). Salaries, £250 and £175 per annum respectively.

ROYAL NORTHERN HOSPITAL, Holloway, N.—Anaesthetist. Honorarium, £100 per annum.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Laboratory Research Worker. Salary, £500 per annum.

TENBIDGE WELLS GENERAL HOSPITAL.—House-Surgeon. Salary, £160.

WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck Street.—Honorary Medical Officer in charge of the Electrical Department.

W. Road, W.—(1) House-Physician. Non-resident Casualty Officer. Salary, £550 a week.

WESTMINSTER HOSPITAL, S.W.—Medical Registrar and Casualty Medical Officer. Honorarium, £150 per annum.

WONCESTER GENERAL INFIRMARY.—Resident Medical Officer. Salary, £200 per annum.

YORK CITY COUNCIL.—Assistant Medical Officer of Health and Assistant School Medical Officer (female). Salary, £500 per annum, or £400 if resident in Maternity Hospital.

CERTIFYING FACTORY SURGEON.—The following vacant appointment is announced: Pontardawe (Glamorgan).

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

ANDERSON, J. S., M.B., Ch.B. Aberd., D.P.H., Assistant Medical Officer of Health, City of Aberdeen.
MIDDLEMISS, K. C., M.B., Ch.B. Glasg., Medical Superintendent, Monsall Hospital, Manchester.

CERTIFYING FACTORY SURGEONS.—M. W. Paterson, O.B.E., M.C., M.B.C.S., L.R.C.P., for the Hyde District, co. Chester. F. B. Croucher, M.B., C.M. Aberd., for the Oxted District, Surrey.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTH.

CLARK.—On August 21st, at "Roscona," Lichfield Street, Walsall, the wife of James A. M. Clark, M.D., D.P.H., of a son.

An Address ON THE INDICATIONS FOR, AND LIMITATIONS OF, SURGERY IN CHRONIC ABDOMINAL DISEASE.*

BY
JAMES SHERREN, C.B.E., F.R.C.S.,
SURGEON TO THE LONDON HOSPITAL, ETC.

IN speaking of the indications for, and limitations of, surgery in chronic abdominal disease I am using the word "surgery" to mean operative surgery—in itself a limitation, as this form of treatment involves the removal of organs or parts of organs, their drainage, short-circuiting, or fixation. We appear to have reached a stage at which operative technique has progressed more than diagnosis, and treatment is often in advance of, and may be more severe and dangerous than, the "disease" for which it is recommended.

Surgery, of course, is not so limited and cannot be divorced from medicine. The surgeon needs to be a physician, and it rightly falls to his lot to suggest and supervise courses of treatment other than operative. At the present time, however, most patients are sent to him when rest, diet, and drugs have failed to relieve, to see if by his art he can remove the cause of the symptoms or in some way alter the relationships of organs that it ceases to act.

Our aim should be to discover the cause of the disease, and so prevent the development of lesions necessitating for their treatment mutilating operations, such as removal of the gall bladder, spleen, portions of the stomach or intestine. We know that long life in comfort and perfect health is possible after all these procedures, but he would be a bold man or surgeon who would assert that the patient who has lost portions of his internal anatomy or whose internal physiology was altered by short circuits is in no way worse off than one not so treated, although we know that he is infinitely better off when disease has been cured or relieved by these means.

It may be with us surgeons as with the sailors of the last century. When the art of building sailing ships and sailing them reached its zenith, so the need for these arts declined, and is now almost lost. It is possible that operative skill will become similarly unnecessary, except in dealing with the result of accidents.

We should not be obsessed with the idea that there must be an operative cure for all abdominal ills, and allow the fact that many abdominal operations can be done at small risk and with little discomfort to lead us to perform or advise operations on speculative grounds.

There is no doubt of the necessity of operation at the present time in dealing with many forms of chronic abdominal disease. In malignant disease its localization is an indication; its secondary deposits a limitation. Although we are still ignorant of its cause, I have no doubt that in the abdomen its onset may be prevented in many cases. There is a preventive surgery as well as a preventive medicine. Timely appendicectomy will, I am convinced, anticipate the development of many ulcers of stomach and duodenum and disease of the gall bladder; but the appendix must be a diseased one—wholesale removal of this organ in cases of viscerotaxis, sacro-iliac strain, etc., only brings surgery into disrepute. The early and efficient treatment of acute gastric ulcer may hinder its change into the chronic type, and early operation on the latter will certainly prevent later malignancy. Similarly, removal of the diseased gall bladder will do away not only with the risk of recurrence of gall stones, when undertaken in cases with this complication, but the possibility of the later development of carcinoma—a risk by no means negligible following cholecystostomy. Drainage of the gall bladder is not curative; all sufficiently diseased to need operation need removal, and there is no more satisfactory operation in surgery that can be undertaken at so slight a risk.

It is essential that diagnosis precede treatment, although that diagnosis may not be made until the abdomen has been opened, but no lesion diagnosed then on symptoms only should ever be treated by surgical procedure; no organ should ever be removed or any mechanical alteration made except for disease that can be definitely recognized—never for symptoms thought to be attributable to a certain organ.

Although diagnosis may be impossible until the abdomen

has been opened, every endeavour must be made, by every method at our disposal, to come to a pre-operative decision as to the cause of the symptoms. We must at any rate be able to say, Surgery will benefit this patient; there is a lesion here that needs operative treatment. It should not be a case of look and see if anything can be done. We should blush to find on opening the abdomen that no demonstrable lesion is present.

In abdominal surgery attention must not be directed only to the organ thought to be at fault; the viscera have interrelationships. When operating for chronic disease the whole abdomen must be explored, and the exploration must be thorough. I have frequently given examples of this and have often had to operate on patients with disease of the gall bladder, stomach, or duodenum in whom I have been informed that this was absent because an incision had been made, the appendix removed, and these organs investigated by touch. It cannot be said too often that disease of the gall bladder—including one of its results, stones—cannot always be diagnosed by touch, and it is often necessary to open it and inspect, even to discover these. Only last week I operated on two patients; in both the gall bladder to the onlooker looked healthy. In one there was thick bile, cholesterol deposits in its mucous membrane, and polypoid cholecystitis; in the other, stones that could not be felt externally. If I suspect gall-bladder disease I always open it and investigate.

Again, how many ulcers of the duodenum or stomach is it possible to feel with the tips of the fingers from below, and how many are missed through making a small incision and exploring digitally? Surgeons should not limit themselves in this way. We used to pride ourselves on being able to remove an appendix through an inch incision; it can be done, but is not surgery.

In treating chronic gastric and duodenal ulcer we should remember that we are dealing with the end-result of disease of which we can at present only discern dimly the cause. The future treatment I believe will not be operative; its indication now is failure to cure or alleviate by medical means. This includes treatment of all foci of infection—rest in bed, diet, etc.; when all these fail surgery is indicated. We must realize that this necessarily involves interference with the physiology of digestion, whether the operation is a short circuit or removal of a portion of the stomach. Operative success in treatment is impossible without altering normal relationships, and the human organism has to adapt itself to it, and does so very well.

Each disease has its own dangers, and operation is indicated on failure of medical treatment because of the grave risk in chronic gastric ulcer of the development of carcinoma, of haemorrhage and less, of perforation. The risk of the development of carcinoma is a very real one. It is no uncommon thing to find on operating on patients with long standing histories pointing to gastric ulcer that carcinoma has supervened and is now beyond the skill of the surgeon. I have found, in a fairly extensive operative experience, that in at least 45 per cent. the carcinoma has followed on chronic gastric ulcer. Others put the figure much higher. Haemorrhage from chronic ulcer is a complication second in severity only to perforation, and one that should be prevented by timely surgical intervention. When it has occurred, operation should be carried out so soon as the condition of the patient will admit. I like to do it within twenty-four hours of the first attack. Many of these resemble secondary haemorrhage, with which you were unfortunately so familiar during the late war; after a warning there is a latent period followed by haemorrhage which not infrequently continues to a fatal issue. I am speaking now of haemorrhage in patients suffering from chronic ulcer—that is, in those with a long-standing history of attacks of indigestion separated by periods of health. It does not apply to haematemesis arising in some cases from acute ulcers, that can be conveniently grouped under the heading of gastrostaxis. These do not need operative treatment. We must not, however, let ourselves be hypnotized by such a word, but always be on the lookout to recognize the cause in each case, and remember that an acute haematemesis is sometimes the first symptom of carcinoma of the stomach and the first symptom attracting attention in splenic disease amenable to surgical treatment.

Operation is advisable in chronic duodenal ulcer, because of the great risk of perforation and haemorrhage. All who have had much experience in the treatment of this grave disease will recall instances in which perforation occurred during a period of latency, between the attacks, when the

* Given at the Annual Meeting of the Suffolk Branch of the British Medical Association on June 30th.

patient considered himself well. No one with this disease, whatever precautions he may take, can consider himself safe from this complication. In many patients the attacks may not interfere much with their life, but it is the risk that makes me advise operation in every case that has resisted efficient medical treatment.

After operations for chronic gastric or duodenal ulcer, notwithstanding altered relationships, the patient is relieved in the majority of cases, and in 90 per cent. is cured, whether the treatment applicable has been posterior gastro-jejunostomy or partial gastrectomy. Failures there must be in everything in this life, in surgery as in all other mundane affairs; these are our limitations, and are mostly due to the impossibility of discovering a still active causative agent, and the recurrence of ulceration in the region of the new opening after operation for chronic duodenal ulcer, or, in still rarer instances, to mechanical changes which may arise in the region of the anastomosis due to the formation of adhesions and resulting in vomiting.

The indications for removal of the appendix are obvious in chronic disease of the type associated with attacks of general abdominal pain with tenderness in the right iliac fossa. It is in these cases that it is justifiable to operate through a small muscle-splitting incision.

It is still necessary to remonstrate against removal of the appendix for pain confined to the right iliac fossa or right side of the abdomen; this is still being diagnosed as due to the appendix, and this organ is being removed without success in its treatment. Hardly a week passes in which I do not see patients in whom this operation has been done unnecessarily and unsuccessfully. Appendicectomy is now so safe that there is very great danger of it being carried out indiscriminately for discomfort rather than for disease and after insufficient investigation. A pain in the right side and tenderness on palpation are not sufficient justification for operation.

It is at present one of our limitations that we have not discovered a satisfactory cause for many of the pains in the right iliac fossa, met with particularly in women. Kidney diseases, ovarian tumours and tubal disease, atony and prolapse of the caecum, intestinal stasis may all be considered responsible, and if due to the first three groups can be cured by surgical means; it is doubtful, however, if this is possible with the remainder; in the majority of these we cannot discover any really satisfactory cause. All, however, need the closest investigation, and care must be taken not to overlook pain due to disease of the kidney and to chronic obstruction, particularly in the pelvic colon, in which the pain may be confined to the right iliac fossa.

Removal of the appendix cannot be expected to cure disease of the gall bladder, stomach, and duodenum; yet how often do we see patients with obscure abdominal symptoms in whom the appendix has been removed through an incision which makes thorough abdominal exploration impossible. Our tactile sense will not diagnose early, and sometimes even late, conditions here. I have long taught, and will once again repeat it: You may diagnose appendix dyspepsia, you should never act on it—that is, you should never remove the appendix alone in these cases and wait for events, but examine every other abdominal viscus. These are the cases of chronic appendicitis in which it is not justifiable to operate through the muscle-splitting incision in the right iliac fossa. For example, last week I operated upon a male patient of 25 with a history of attacks of indigestion for four years, whom I had been asked to see as a case of appendix dyspepsia. The report of the barium meal was a normal stomach; his test meal gave normal gastric acidity. I removed a thickened appendix becoming obliterated at its distal end and then prolonged the incision upwards. I found a chronic ulcer on the lesser curvature about an inch from the pylorus. This is the most recent example, but I have had a similar experience on many occasions, on more have had to reoperate after others, and have found not only chronic ulcers and gall-bladder disease, but even carcinoma of the stomach, after the appendix had been removed on the diagnosis of appendix dyspepsia.

It is one of the limitations of abdominal surgery at the present time that it is impossible to exclude disease without examining by sight and touch the suspected organs. When abdominal symptoms are present they may be definite enough for us to say they are due to disease of the gall bladder, the duodenum, the stomach, or the appendix, but we cannot say that there is no disease in either of the other organs without looking. In the type of case, by no means uncommon, in which, in spite of every method of investigation, we are uncertain of our

diagnosis, all have equally to be examined. Our limitation will be fewer if we remember that the days of small incision are over. If a paramedian incision is used, pulling the rectum out its length does not matter. I would remind you that in chronic abdominal disease the organs with which we have to deal are situated principally to the right of the mid-line, yet I still see patients who have had a "gastro-jejunostomy" performed or even an exploration carried out through a left-sided incision.

When dealing with the colon one enters at once into a region where there has been and still is fierce controversy. We are, however, on absolutely solid ground when we give as an indication for surgical treatment the removal of portions of the colon that are so diseased as to be incapable of performing their function. The operative surgery of malignant disease here, as elsewhere, has its limitations in spread of the disease outside the limits of the organ; the problem of treatment consists in removing sufficient bowel together with its lymphatic area of drainage. In non-malignant conditions every endeavour should be made to conserve the colon, and, if excision is necessary, to remove as little as possible. In dealing with the caecum and ascending colon we must bear in mind that removal of the ileo-caecal valve profoundly alters intestinal digestion. Removal of the colon or its right half must interfere seriously with the functions of the alimentary tract. The colon is necessary in the human economy; it should never be removed unless its retention threatens life.

In chronic ulcerative diseases not cured by medical measures appendicectomy in my hands has given brilliant successes, but there are failures. In these I have brought up a coil of the ileum about a foot from the ileo-caecal valve and drained it so as to give the colon absolute rest, and not restored the continuity of the alimentary canal until examination of washings has proved the ulceration to be healed. Ileo-sigmoidostomy is useless in the treatment of ulcerative colitis; it is an operation that is rarely, if ever, justifiable; it does away with the action of the ileo-caecal valve, and does not prevent overfilling of the colon proximal to the anastomosis. If a short-circuiting operation is necessary in the treatment of irremovable carcinoma of the colon it should be colon to colon.

We come now to a group of cases with which all are familiar, under the term "visceroptosis." Much more often met with in women than in men, it is a continual source of invalidism, if not of real ill health. It is therefore not surprising that patients seek, and surgeons have endeavoured to find for them, relief by operative means. Many are the operations that have been devised and carried out: division of adhesions, plications, fixation of stomach and colon, even to colectomies, partial or complete, with, I believe, no more success than will attend a similar compulsory rest in bed. The more experience I have in abdominal surgery the less success do I expect from operation in these cases and the more loath am I to undertake it. We are driven to it sometimes by the limitations of our knowledge; it may be quite impossible to exclude other and more serious disease without exploration. Gall-bladder disease is common in this type of case. Chronic gastric ulcer high on the lesser curvature is not infrequent, and carcinoma may develop.

Always remember that it is not a disease that shortens life; carry out nothing that may do so. I believe many of these patients are suffering from disease of their autonomic nervous system—that the visceroptosis, the dropped stomach, atonic and prolapsed colon are not causes. They may all exist without producing symptoms, and those that occur cannot always be explained by their presence. Diagnosis has outrun treatment here. Surgeons were justifiably eager to seize upon these "misplacements," just as in earlier years displacements of the uterus were looked upon as the source of chronic ill health. From the experience we have gained in its surgical treatment I believe that in its management such operations as fixation of colon, partial colectomy, plication of caecum, will disappear.

We must realize our limitations here, while trying in every way to improve our methods of diagnosis. There are still pains and discomforts in the abdomen that cannot be removed with the appendix or by fixing viscera or dividing adhesions.

To pass now to the gall bladder. Here our limitations are less, as we are able to deal with the disease and not only remove its results. At the present time, only operation can demonstrate the condition of the gall bladder. I would again lay particular stress on the fact that until the gall bladder

has not only been seen but explored by opening, it is impossible to be certain that disease is absent. In the early stages of gall-bladder disease cure by surgery is sure and safe; in the presence of such complications as stone in the common duct and acute infectious the risk becomes greater, and malignancy may be the termination of chronic simple gall-bladder disease.

When the gall bladder is diseased its removal is indicated—in two stages, if life or the integrity of the common duct is threatened if done in one. Drainage alone will not certainly cure, nor will it prevent the later onset of carcinoma in gall bladders believed, on external examination, to be healthy at the time of drainage, after removal of calculi. I have known it to arise from one to four years after drainage of what was considered a sufficiently healthy gall bladder to leave after the removal of calculi.

One of the most recent advances in abdominal surgery is that dealing with disease by splenectomy. Although we know that removal of the spleen is followed by restoration to health in suitable cases, until we are fully cognizant of its functions we cannot understand the part it plays in disease and why removal in certain cases is efficacious. That long life was possible after removal of the spleen in man we owe to clinical observation after splenectomy for injury. Interference next followed in such conditions as wandering spleen with torsion of the pedicle or the rare tumours. More recently, diseases of the spleen associated with blood changes have been successfully treated; I allude to such groups as splenic anaemia, Banti's disease, and splenomegalic jaundice. In the former, restoration to health occurs, and so far as we can ascertain no evil effects follow; we can justifiably speak of cure. It may be otherwise when operation is carried out in the later stage of the disease when cirrhosis of the liver has supervened. With this complication, when haemorrhages have taken place before operation, although apparent restoration to health is the rule, yet death from haematemesis at a later date is not unknown, in spite of the fact that splenectomy has been suggested as the treatment for certain cases of haematemesis in the absence of gastric or duodenal ulcer, splenomegaly, or recognizable hepatic cirrhosis. Our limitation here is due to neglect of treatment in the early stages of the disease.

Of the cause of the disease and the splenic enlargement, whether due to thrombosis—and if so, the infecting agent and its organ—we are in ignorance. Why removal of the spleen alters the blood picture is also beyond our ken. We are sadly limited in our dealings with diseases associated with splenic enlargement in not knowing their cause.

I know of no condition in which recovery is so dramatic as in splenomegalic haemolytic jaundice. In the familial type discoloration may have persisted from the early years of life, and yet within forty-eight hours of removal of the spleen it has disappeared. The fragility of the red cells, part of the disease, may be unaffected by splenectomy. As in other chronic abdominal diseases, general exploration has to be carried out, particular attention being paid to the gall bladder and ducts, as these cases are often complicated by pigment calculi.

Splenectomy in pernicious anaemia and in leukaemia is experimental, and until more evidence is forthcoming we should stay our hand.

Surgery has many legitimate triumphs in the abdomen. Let us see to it that it is not brought into disrepute by operations for trivial complaints, and that removal of the appendix or gall bladder, or fixations of the colon, do not become common procedures in every discomfort in this region.

PAIN IN GENITO-URINARY AFFECTIONS:

ITS VARIATIONS AND THEIR INTERPRETATION.

BY
W. K. IRWIN, M.D., F.R.C.S. (ENGL.),

HONORARY CASUALTY OUT-PATIENT SURGEON, ST. PAUL'S HOSPITAL
FOR GENITO-URINARY DISEASES.

The variations of pain in genito-urinary affections are so numerous and often so misleading that their interpretation may be difficult. It is hoped that the following notes will facilitate the early recognition of the causes at work.

Pain arising in this system frequently shows itself in parts other than the seat of the lesion, and it may be well at the outset to emphasize the distinction between (1) *sito pain*, which is felt in or over the lesion, and (2) *referred pain*,

which through abnormal perception by the senses is assigned to the region supplied by an anastomosing nerve trunk or to the distribution of an irritated nerve.

Renal and Ureteric Regions.

Affections of the kidney are comparatively painless if the ureters remain patent. *Renal calculi* may give rise to three varieties of pain: (1) *sito pain*, (2) *referred pain*, (3) *renal colic*. The *sito pain*, which is more prominent during the diurnal hours of activity, is a dull-ache, and is felt in the front of the loin, in the posterior renal angle behind, or in both places. The *referred pain* may be assigned to the healthy kidney (reno-renal reflex), testicle or labium, bladder, urethra, thigh, knee, calf, inside of foot, sole or heel, and may be of a burning nature. In renal colic the pain, which may be described as "tearing or gripping," is characterized by agonizing paroxysms radiating down the line of the ureter and along the urethra, or referred to the external abdominal ring and into the testicle, causing contraction of the cremaster muscle.

Oxaluria may cause unilateral pain similar to that of renal calculus. Such pain as there may be in *tuberculous kidney* is a dull lumbar-ache described as toothache-like, though tuberculous debris in a ureter may cause ureteric colic. *Movable kidney* is characterized by a dragging ache, aggravated by movement, but the kinking of a ureter in a Dietl's crisis may produce pain, resembling the colic caused by a calculus. In *kidney tumour* pain, which is not increased by movement, may result from increased intrarenal tension, from ureteral obstruction by blood clot, or from pressure on surrounding structures. *Ureteral calculi* usually give rise to symptoms akin to those of renal calculi, the pain being due to the distension and spasmodic contraction of the kidney pelvis and of the ureter above the stone rather than to the irritation produced by the stone itself. Pain of a similar character may be caused by an aberrant blood vessel, by stricture or kinking of the ureter, or by its becoming blocked by tuberculous debris, blood clot, or a villous growth of the kidney pelvis.

Vesical and Urethral Regions.

Apart from acute blocking of the ureter genito-urinary pain as a rule has its source in the bladder, prostate, or prostatic urethra. Pain originating from the upper half or more of the bladder is usually felt above the pubis, but pain from the ureteric orifices and adjacent part of the bladder wall is sometimes referred to the corresponding inguinal ring or along the corresponding side of the penis. Perineal pain suggests disease of the vesical base or neck, of the prostate, prostatic or membranous urethra, or of some structure intimately associated with one of them, constant chronic pain being in most cases due to prostatitis, or to carcinoma or calculus of the prostate, and pain increased at the end of micturition to calculus, inflammation or ulceration of the bladder; but in any of these conditions the pain may be referred to the end of the penis. Urethral pain if before micturition is usually caused by obstruction from impacted calculi, etc.; if only during micturition, by inflammation or ulceration of the urethra.

Pain due to *vesical calculus* is usually felt at the end of micturition, and may be stinging or sharp and cutting. It is usually felt at the neck of the bladder and in the urethra slightly behind the external meatus, but may be felt in the perineum and at the root of the penis. In children it is often very severe, the patient screaming and pulling at his foreskin, especially at the end of micturition; but in old patients if the stone lies in a post-prostatic pouch, so as not to come in contact with the vesical neck, little if any pain may be felt. The pain may gradually decrease owing to the calculus becoming larger and smoother by the deposit of phosphates around it. The effect of rest upon pain due to vesical calculus is so great as to be an important diagnostic sign.

Such pain as is caused by *calculi of the prostate* is usually felt only during and after micturition, but there may be a constant ache increased by defaecation and unconnected with micturition, while in *calculi of a seminal vesicle* painful defaecation and seminal ejaculation may occur. *Acute cystitis* produces scalding pain along the urethra during micturition, while at the end of the act, or if the patient tries to hold his water, there may be pain in the region of the vesical neck. In tuberculous cases severe pain as a rule indicates ulceration of the trigone or the onset of mixed infection. The features of pain in *acute urethritis* and *prostatitis* are too familiar to need any description. *Acute spermatoecystitis* is associated

with deep pain in the perineum, pain on defaecation, and perhaps pain in the sacrum, testicle, or hip-joint. In vesical tumour there may be pain due to cystitis, blood clot blocking the urethra, ureteric obstruction, or pressure upon nerves. The pain may at first be unilateral, pointing to the growth being on the corresponding side of the bladder. In carcinoma of the prostate the pain, which is unconnected with micturition or movement, is usually a constant dull ache, but is sometimes severe and may be referred to the suprapiubic region, hip-joints, thighs, testicles, etc., and is for sciatica.

Patients may complain of agonizing pain in the bladder, perineum, etc., and of other symptoms for which no adequate explanation can be found; but before diagnosing the condition as neurotic careful search must be made for an organic cause, and commencing spinal disease must not be forgotten.

TWO CASES OF INTRACRANIAL COMPLICATION OF ACUTE EAR DISEASE.

BY

PETER MACDONALD, M.D.,

SENIOR HONORARY SURGEON, EAR, NOSE AND THROAT DEPARTMENT,
YORK COUNTY HOSPITAL.

AND

J. ACOMB, M.B., B.S.,

ASSISTANT HONORARY SURGEON, EAR, NOSE AND THROAT DEPARTMENT,
YORK COUNTY HOSPITAL.

THE two cases described below of intracranial complication of acute otitis media were in-patients at the York County Hospital, one under the nominal care of one of us, the other of the other. The treatment, however, operative and other, as well as the process of diagnosis, was the joint work of both of us, so that they may be regarded as patients common to us jointly. They both present unusual features which seem to us to make them worth recording.

E. J., a man aged 36, was admitted on January 19th, 1922. Ten days previously he had had "influenza," and about a week previously, about January 12th, he became deaf in the right ear, and this ear began to discharge. A day or two later he became deaf in the left ear; but this ear did not discharge. There was a doubtful history of a rigor on January 18th, the day before admission.

On admission, both mastoid processes were somewhat tender; the patient was very deaf in both ears. The right drum membrane was acutely inflamed, and there was discharge from the tympanum. The left meatus was full of wax, and on removal of the membrane was found somewhat inflamed, but not apparently bulging. The temperature was about 100°. There was some very slight swelling and redness of the right optic disc, and a doubtful swelling of the left disc. The patient was somewhat dull and lethargic, but did not appear very ill.

The right mastoid process was operated on the same evening. The mastoid cells were inflamed, and many of them contained granulations; but there was very little, if any, free pus. The lateral sinus was laid bare, but appeared to be healthy. The left drum membrane was freely incised.

Next day the conditions seemed to have improved, and there was but little change for a week, the temperature fluctuating between 98.4° and 100°. There was little, if any, discharge from the left ear. The general condition improved; there was less drowsiness and lethargy. The swelling of the optic discs, however, increased, and on January 25th a hæmorrhage was noticed in the neighbourhood of the left disc.

On the evening of January 26th he had a rigor, and the temperature rose to 105.8°. A diagnosis of thrombosis of the lateral sinuses, which had formerly been suspected, was now definitely made, and it was decided to explore the sinuses. The right sinus was inspected, there being but small evidence of any serious trouble on the left side. There was, in fact, little evidence, except deafness, of any trouble on the left side. The right sinus was accordingly laid bare at greater length. It looked healthy, but a needle was inserted into the sinus and blood aspirated from it. Blood came away freely, and it was evident that the sinus was not thrombosed, at least above the level of the jugular bulb. It was thought that the vein might be thrombosed at the bulb, and so the internal jugular was exposed in the neck, but it was quite evident that there was no thrombosis.

In view of the presence of the optic neuritis we decided, although there was no other evidence of brain abscess, to explore the temporo-sphenoidal lobe. The tegmen antri was removed, and an area of dura exposed. There was no extradural abscess. The dura appeared to be bulging. We opened it and passed a sinus forceps in several directions into the temporo-sphenoidal lobe, but no pus was found.

We were nonplussed. We had found nothing to account for the condition, and after a hurried consultation we decided to explore the left mastoid and left lateral sinuses. The mastoid process was accordingly rapidly opened. The mastoid cells were inflamed and many of them filled with granulations, and on laying the sinus bare it did not look healthy. A syringe needle was inserted into the

sinus, and no blood could be aspirated from it. The jugular vein was rapidly exposed in the neck and tied above the common facial, and the clot curetted out of the sinus until blood flowed freely from its upper end. The petrosals were evidently not thrombosed; so that the upper portion of the jugular vein had to be kept tied, and we were unable to wash through from the sinus. The temperature next day was normal. It rose on January 28th, and remained between 99° and 100.5° until February 9th. It is probable that this was due to pus in the upper portion of the jugular vein and bulb into which the septic thrombus broke down.

The pathologist's report showed that the blood aspirated from the right sinus was sterile, and a culture from the thrombus on the left side contained streptococci.

The condition of the patient continued to improve, except that the optic neuritis persisted, until February 20th, when he became drowsy and lethargic, and further operation was arranged for on February 21st. But on dressing the right ear on the morning of that day a copious discharge of pus was found in the right mastoid wound, apparently from the region of the exposed dura of the temporo-sphenoidal lobe, although the wound had so closed up that the source could not be precisely determined. From this time the patient made an uninterrupted recovery, and the optic neuritis rapidly disappeared. He was discharged on April 22nd, with both wounds healed, and hearing in both ears was good. He has been seen recently, and is in good health.

The course of events can now, in retrospect, be fairly well established. An infection of both middle ears was contracted, and while there was no violent inflammation of either mastoid process, there was an extension of the inflammatory process on the right side into the temporo-sphenoidal lobe, setting up a slow abscess there, and on the left side to the lateral sinus, setting up a septic thrombosis. By opening up the right temporo-sphenoidal lobe we allowed of an ultimate escape for the pus there, although we did not actually strike the abscess, which was undoubtedly present. On the other hand, had we struck the abscess at the time of the operation on January 26th it is quite likely that we might have been satisfied that we had found enough to account for the symptoms, and might not have attacked the thrombosis of the left sinus until too late. Had the abscess not evacuated itself spontaneously on February 21st we should most likely have attacked the left temporo-sphenoidal lobe before going back again to the right in view of the presence of the neighbouring septic condition in the right sinus. As it was, we did just enough to allow of recovery, and freely admit that this was largely a matter of good fortune in what was a puzzling case.

The second was a case of middle-ear disease, complicated by infection of the mastoid antrum and cells, and sinus thrombosis. The special feature was the extent of the thrombosis and the comparative mildness of the symptoms.

H. H., male aged 19, had a history of carache from the age of 6 years with intermittent discharge from the right ear, especially after he had "contracted a cold."

He was admitted to the hospital on November 19th, 1921, suffering from a scanty discharge from the right ear, and was feeling ill and shivery. The temperature was 102°; pulse rate 84, respiration rate 20. The right tympanic membrane was incised and a discharge of serum and blood came away. The following day he felt better, but later he had a rigor, with a temperature of 105° falling, with profuse perspiration, to 99.5°. We decided to open up the mastoid and explore the sinus. The mastoid cells and antrum were found to contain pus and granulations. The sinus was pulsating freely and appeared normal. It was explored and found to contain thin pus. The internal jugular was exposed in the anterior triangle; it had become practically converted into a bag containing fluid pus. The vein was divided, but it was found impossible to reach the lower limit of the sterno-clavicular articulation, was followed down to the level of the sterno-clavicular articulation. The sinus was followed backwards and to the bulb; it was opened and as much of the clot and thin pus removed as possible. Neither end of the vein was tied.

Bacteriological examination of a specimen taken at the time of operation was reported as a pure culture of streptococci. Intravenous injections of polyvalent antistreptococcal serum were given. Three days after operation streptococci were reported as being present in a blood specimen taken. An autogenous vaccine was prepared and given.

The progress of the case was uneventful, and on February 1st, 1922, the patient was discharged, his condition, according to our notes, being as follows: "Looking very fit. No dressing needed for mastoid or scar in the neck."

The remarkable features appeared to us to be the mildness of the symptoms considering the extent of the disease, the absence of pain over the classical sites, the extent of the thrombosis, the absence of pyæmic complications despite the presence of fluid pus in the jugular vein and of streptococci in the general blood system, and the impossibility of removing the whole of the infected material.

Our thanks are due to our house-surgeon, Dr. Janet Nicol, for her supervision and notes of these cases.

NINETIETH ANNUAL MEETING

OF THE

British Medical Association.

Held at Glasgow, July, 1922.

PROCEEDINGS OF SECTIONS.

SECTION OF OTOTOLOGY.

ALBERT A. GRAY, M.D., F.R.F.P.S., President.

DISCUSSION ON

SEPTIC SINUS THROMBOSIS: ITS DIAGNOSIS AND TREATMENT.

OPENING PAPERS.

I.—DIAGNOSIS OF SEPTIC SINUS THROMBOSIS.

BY

SIR WILLIAM MILLIGAN, M.D.,

Lecturer on Diseases of the Throat and Ear, University of Manchester.

MR. PRESIDENT AND GENTLEMEN.—The presence of a thrombus in the lateral sinus is in effect an effort on the part of Nature to protect deeper-seated and more vulnerable structures. The most usual site of its location is in its sigmoid section, the next most frequent in its bulbar portion. So long as the thrombus remains sterile no particular harm results; but when infected, as practically invariably happens within a few days of its formation, a state of affairs detrimental to the health and inimical to the life of the individual is at once established. That its presence is at times overlooked, and a diagnosis of typhoid fever, bronchopneumonia, or malaria made, is unfortunately still too true.

The causative organism is, in my experience, invariably the streptococcus, and frequently the *Streptococcus haemolyticus*, but that its virulence and its toxicity vary in different stages in the progress of the disease is, I think, undoubted. I am disposed to think, however, that the ever-varying anatomical structure of the temporal bone and the relative position of the sinus to adjacent mastoid cells is of even more importance in the incidence of the disease than the virulence of the causal organism. A preliminary x-ray examination gives in certain cases a general idea of the geography of the petromastoid region and sinus groove, but, generally speaking, owing to the more or less acute illness of the patient it is seldom applicable as a diagnostic aid.

Thrombosis of the sinus is more likely to occur in the pneumatic than in the diploetic variety of mastoid. In typical and in advanced cases diagnosis is as a rule not difficult, the remittent type of temperature, the rigors, the profound asthenia, the localized pain over the sinus and along the course of the jugular vein, at times accompanied by torticollis, presenting an almost unmistakable clinical picture. The right sinus is more frequently involved than the left, and sinus infection is more common in males than in females. It is the atypical case and the latent case, both by no means uncommon, which present diagnostic difficulties to even the most experienced, and yet it is an early and accurate diagnosis which tells almost more than anything else in the successful treatment of this particular affection.

Atypical cases, which, in my experience, are more frequently met with in children than in adults, are due at times either to dehiscences in the tympanic floor or to its extreme thinness with consequent infection of the bulb. In such cases no demonstrable symptoms of mastoid infection may be present. At other times the presence of a very forward sinus and an almost complete absence of mastoid cells is the responsible factor. To await the development of the full array of classical signs and symptoms is merely to court disaster. An intelligent appreciation and anticipation of the course of pathological events will materially assist in helping to make an early diagnosis, and an early diagnosis should spell early operative interference in order to prevent the advent of general septic poisoning.

The stage at which sterility of the existing thrombus gives place to infectivity is the all-important phase of the disease, and the one to which our thoughts should be mainly directed,

for if only we could assure ourselves from clinical data of the precise moment at which this change takes place the chances of saving the patient's life would be materially increased. It is to this problem that I desire more especially to direct your attention.

On examining my records of intracranial complications secondary to purulent otitis media I find that thrombosis of the lateral sinus occurs in, roughly speaking, 50 per cent. of these cases, while septic meningitis occurs in nearly 60 per cent. Both complications tend to be solitary complications, but whereas meningitis is almost invariably fatal, sinus thrombosis has, if operated upon at a sufficiently early stage, the merit of being more amenable to surgical interference than any of the other intracranial complications usually met with.

The special proclivity to sinus infection as a complication of purulent otitis media is, I hold, to be explained mainly on anatomical grounds, the actual position of the sinus being very inconstant—at times situated quite superficially and approaching close to the posterior meatal wall, at other times lying deeply and separated from it by a considerable thickness of cellular bone. In brachycephalics it is said to be situated farther forwards and outwards than in dolichocephalics.

In the first place, the peculiar and intricate structure of the middle ear tends to prevent free drainage of tympano-antral suppuration; in the second place, and as a direct consequence of the frequent absence of free drainage, the temporal bone is peculiarly prone to septic infection; while in the third place, the relation of the lateral sinus to the mastoid antrum and to the numerous venous radicles which, running through the temporal bone, ultimately enter it, renders it specially liable to organismal attacks. Moreover, as the sinus is an interdural structure it is consequently more vulnerable than a structure separated from an existing septic focus by the full thickness of a normal dura mater.

While thrombosis of the sinus almost invariably occurs as the result of a chronic infective process, it must be borne in mind that it is by no means infrequently encountered during the acute stage of an otitis media, when its presence is prone to be overlooked, the infective path being either directly along venous radicles between the middle ear and the sinus, or by way of small venous tributaries connecting the tympanic mucosa with the petrosal sinuses.

Thrombosis secondary to acute septic otitis media is, in my experience, however, less dangerous than when secondary to chronic otitis media. It also occurs in cases where there has been merely a fleeting tympanic suppuration, or where it has entirely ceased, and the previously ruptured membrane healed. This is due to the fact that, in the course of the tympano-antral suppuration the middle ear becomes occasionally entirely shut off from the antrum as the result of the fusion of granulation tissue in the "iter." I have seen several such anomalous cases myself, and others have been recorded by Mollison, Piolti, Friedmann, Greenfield, and others.

While sinus infection is usually due to extension of an existing bone lesion, it may also result from direct venous infection—for example, by way of an unobliterated petrosquamosal sinus, by way of the petrosal sinuses, or as the result of pus spreading between the dura and the petrous pyramid upon either its anterior or posterior surface. The resulting phlebitis may end in the formation of mural thrombosis or in complete obliteration of the sinus.

Thrombosis of periphlebitic origin is not only more gradual in its onset on account of the frequent presence of a barrier of protective granulation tissue, but is also more likely to end in perforation of the coats of the sinus wall, with the ultimate formation of an abscess in continuity with the area of suppuration within the mastoid cells.

Thrombosis of endophlebitic origin, where the infection is conveyed directly by the blood stream, is unattended for a considerable time by visible changes in the superimposed tissues or in the vessel wall, produces general infective symptoms more rapidly, and is thus the more dangerous type of infection. It is of the utmost importance that we should endeavour to discover from clinical signs and symptoms that phase of the disease where we have to deal with a non-infected clot and that phase when the clot has become infected. The presence of a non-infected clot is an actual safeguard, and if only the local disease be removed at the psychological moment its presence need not give rise to anxiety. If, however, the focal disease be not removed at once secondary infection of the clot is only a matter of a few days.

In any case of middle-ear suppuration, acute or chronic, where reasonable drainage exists, the occurrence of a rigor should always excite suspicion: it is a danger signal of the first importance. Moreover, the continuance of a high temperature for several days after a mastoid operation, especially if the patient be a child, should be regarded with equal suspicion.

The temperature record is, to my mind, one of the most important and reliable of diagnostic signs. To get real assistance from it an almost continuous record should be kept, but failing this at least a two-hourly record. The swinging morning and evening temperature with which we are all so familiar certainly indicates that thrombosis is in full bloom; but what the chart ought to show, and does show if records are made frequently enough, is the time at which disintegration is taking place. Sudden oscillations of more than one to one and a half degrees are unusual in uncomplicated suppurative mastoiditis, but frequent oscillations of from one to three degrees are quite common in commencing peri- or endo-phlebitic thrombosis, and their presence should at once put the clinician on his guard. In young people, among whom, as I have already stated, atypical cases are most frequently met with, temperature is a less exact guide than in adults, the tendency being for it to be continuously high rather than remittent. The pulse rate varies more or less regularly with the temperature, except in cases where an intracranial abscess is also present, when it may become almost nuduly slow.

Too much stress is frequently laid upon the absence of rigors. Their presence, more especially if they recur frequently, is practically diagnostic; but their absence, providing certain other leading indications are present, should certainly not negative exploration. They occur only in about one-half of the cases. So long as the system is capable of throwing off the accumulating toxins there is no special reason why there should be any rigors; when overcharged, however, rigors are frequent. In children they are frequently absent throughout the whole course of the disease.

Chills and a feeling of chilliness are very important symptoms too often overlooked, although they are present in nearly 80 per cent. of cases. Frequent inspection of the hands, feet, and knee-caps should be made, as they are often found cold when the temperature is quite high.

Profuse sweating is by no means always present. At first it occurs as the temperature is subsiding, but in very severe cases may be almost continuous.

Important information, too often ignored, is to be obtained from a daily examination of the retinal veins. Ocular changes occur in some 75 per cent. of sinus cases, but are frequently so slight—although so important—that they may not be appreciated unless frequent examinations are made. An actual optic neuritis, however, occurs in only about 30 per cent. of the cases. As the sinus becomes gradually occluded the ipsilateral veins become slightly engorged owing to the venous "backwash," the contralateral veins remaining normal. A sudden diminution of engorgement indicates either that the thrombus has contracted or that it is breaking down, with the result that infective particles are being floated away in the blood stream. In the former event no rise of temperature takes place, in the latter it suddenly shoots up, and may or may not be accompanied by a rigor. For similar reasons the temporal, occipital, and facial veins, and at times the emissary mastoid vein, may get blocked, with a resulting slight oedema or puffiness of the adjacent subcutaneous connective tissue. When the sinus is occluded the normal venous hum over the internal jugular disappears, but is audible upon the opposite side.

The sign described by Crowe is also at times of value. Pressure upon a normal internal jugular vein produces demonstrable dilatation of the superficial veins of the forehead, eyelids, and temples, and to some slight degree of the retinal vessels, whereas pressure upon an already obstructed jugular vein has no such effect.

If on exposure of the sinus it be found to have a dark bluish colour it must not be taken for granted that no thrombus is present. In thrombosis of endophlebitic origin the walls retain for a considerable time their normal appearance; when of periphlebitic origin, however, their colour is usually grey or a yellowish-grey, protective granulation tissue being also frequently present.

Pulsation of the sinus synchronous with the respiratory movements may or may not be present. Whether present or absent, I have found the sign to be of little value. Diagnostic information of value is, in my experience, very rarely obtained

from a blood count. The presence of a high degree of leucocytosis, or of large numbers of mononuclear leucocytes, is suggestive of pus, but by no means necessarily of pus in the sinus, or even around it. When, however, associated with other suspicious symptoms, it may be looked upon as a helpful aid.

Certain paralytic phenomena are also at times present, as, for example, paralysis of the hypoglossal nerve from the pressure of a thrombosed condyloid vein as it emerges from the anterior condyloid foramen.

When thrombosis of the jugular bulb is present the existing pressure may cause paralysis of the vagus, spinal accessory, or glossopharyngeal nerve. Should extension to the cavernous sinuses take place paralysis of the abducens, the oculo-motorius, or the trigeminus may result.

Differential Diagnosis.

The disease with which sinus thrombosis is most likely to be mistaken is, in my experience, typhoid fever. During the first week of an attack of typhoid many of the symptoms are almost identical with those of sinus thrombosis, and if by chance the patient happens at the same time to have a suppurating ear confusion becomes confounded. The presence, however, of a Widal reaction and petechiae and the absence of very marked variations of temperature with rigors or chills are as a rule sufficiently distinctive.

At times it is difficult to distinguish thrombosis from a central bronchopneumonia. The persistent cough, the rusty sputum, and the more even temperature serve, however, as useful differential diagnostic aids. From malaria it is to be distinguished by means of a blood examination and the discovery of the *Plasmodium malariae*.

In rare cases in infants and young children severe gastric attacks, especially if at the same time the patient has running ears, are liable to mask an existing thrombosis and to confuse diagnosis.

While, Mr. President, all present will probably agree that typical cases present no great difficulty in diagnosis, all will, I think, equally agree that atypical and latent cases present extremely complex problems to the clinician. The value of an early and accurate diagnosis cannot be overestimated. My own practice is to attempt to unravel the complexities of the case as far as possible from clinical signs and symptoms, but when reasonable doubt exists I have no hesitation in performing an exploratory operation, in exposing or actually slitting up the sinus, purely and solely for diagnostic purposes. I have never had any reason to regret adopting this course of action, and have on quite a number of occasions had every reason to be thankful for having adopted it. Surgical surprises are still not uncommon in even the best regulated clinics, and the old adage *humanum est errare* is quite as true to-day as it was in days gone by.

II.—SOME DIFFICULTIES PRESENTED BY CASES OF SEPTIC SINUS THROMBOSIS.

BY

LIONEL COLLEDGE, M.B., F.R.C.S.,

Aural Surgeon to St. George's Hospital, Surgeon to the Throat and Ear Hospital, Golden Square.

MR. PRESIDENT.—It was at your request that I wrote for this meeting a short paper on some difficulties in dealing with cases of sinus thrombosis. Unfortunately, since then Mr. Hunter Tod, who was to have seconded Sir William Milligan in opening the discussion, has found himself unable to fulfil this engagement. Your loss is a severe one, since he has a large experience of this complication of aural disease and the power of clear exposition, so that you would have received from him something far more illuminating and worthy of discussion than I can give you. I have, however, endeavoured to supplement the paper by reference to some of the literature of recent years, so that if it now smells somewhat of the lamp the blame is partly yours, but I hope to present to you some points which will arouse discussion.

Difficulties in Diagnosis.

(a) The condition may be confused with malaria, especially if rigors occur.

A soldier was invalided home from Salonica in order that a mastoid operation might be performed for the cure of chronic otorrhoea accompanied by persistent pain. After three days in England he passed a medical board and was dispatched to the western front, where he served in the trenches for a short time before being once more evacuated. On admission to a clearing

station he was suffering from slight diarrhoea, pyrexia, and severe pain in the left ear, from which there was a foul discharge; his pulse was 120. He stated that he had had malaria in Salonica. Soon after admission the temperature rose still higher, and the patient had a rigor. A radical mastoid operation revealed the ordinary type of caries of the middle ear and antrum; the lateral sinus appeared healthy. This operation caused no alteration in the general condition, and a microscopic examination of the blood, obtained on the following day, revealed numerous malaria parasites. The patient rapidly recovered after the administration of quinine. In this case no harm was done, as the operation was needed in any case, though not perhaps at that moment; but it was felt after consultation with a physician that a mistake in the contrary direction might cost the patient his life.

This difficulty in diagnosis seems to be quite common in America, and perhaps since the war it may have become commoner in this country. Quite recently a young lady developed a temperature of 105° after a mastoid operation, and it was only then learnt that she had been in a tropical country and had had malaria.

(6) It may be mistaken for typhoid fever. My friend Mr. Jasper Blaxland of Norwich has given me the following record:

A woman, aged 32, had been ill for ten days, complaining especially of headache, but had no pain. Her doctor thought her illness might be typhoid fever, but the Widal reaction was negative. She had had bilateral otorrhoea for twenty years following scarlet fever and was very deaf. It was not until the tenth day of the illness that tenderness was noticed over the left mastoid. At the operation performed the same day the antrum and cells were found to contain pus and cholesteatoma. The lateral sinus was covered with granulations. There was at first some apparent improvement, but subsequently the patient had a rigor, and six days after the first operation the jugular vein was ligatured and divided. The lateral sinus, which contained pus, was followed back almost to the torcula. The inner wall of the sinus eventually sloughed, leaving the cerebellum exposed, covered with granulations. A few days later oedema of the eyelids, cheeks, and upper lip seemed to indicate spread of the thrombosis to the cavernous sinns, but these symptoms gradually disappeared. This patient remains well up to the present time, nine years later.

The following case presented great difficulties in diagnosis. Fortunately no mistake was made or the patient's life would have been lost.

A girl, aged 13, had measles. On the ninth day she had a rigor with a temperature of 105° and signs of pus in the right ear. Highmore. The following day and thick pus washed out. Two right mastoid appeared and the mastoid cells and antrum being found full of pus. An opening was also made through the nose into the maxillary antrum with a burr. The antrum was washed out. The temperature and pulse gave no further trouble. The patient was with a high temperature and pulse of suppuration in the left mastoid four days later. The Schwartz operation was therefore performed on this side also. After this the condition of the patient showed no improvement, the temperature rising to 103° at night from normal in the morning, whilst the pulse rate varied from 120 to 140. The lateral sinuses, which had been exposed on either side, appeared healthy, but the wounds remained absolutely inactive with no sign of healing nor the formation of granulations. Applications of hypertonic saline with the object of stimulating the wounds had no effect. The condition of the patient became desperate and a rapidly fatal result seemed almost inevitable, but she improved slightly and a blood culture was taken. The culture showed next day a pure growth of *B. typhosus*. The patient was seen by a physician, who refused at first to entertain the diagnosis of typhoid since the swinging character of the temperature, the extreme rapidity of the pulse, the condition of the abdomen, the nature of the stools, and the absence of rose spots and enlargement of the spleen were all against it. He was, however, unable to dispute the evidence of the blood culture. The patient eventually recovered after a somewhat stormy convalescence, and she remains well with perfect hearing.

Mason¹ has reported a case of thrombosis of the jugular bulb caused by the *B. typhosus*, probably starting in the third week of typhoid fever. The *B. typhosus* was grown in pure culture. This patient recovered after operation.

Although in the exceptional case just mentioned the blood culture proved of great value it is not as a rule of much assistance in the diagnosis of sinus infection. Kopetzky² has well defined its limitations as follows;

"In the finding of streptococci in the blood stream there is substantiation of a diagnosis of sinus thrombosis, all other sources of infection being eliminated; but in the event of negative findings then it is better to operate on the clinical findings than to let pass the time when surgical intervention will result in a successful issue."

(c) Sinus thrombosis most commonly occurs as a complication of chronic otorrhoea, in which case the onset and symptoms are more likely to indicate the diagnosis than if it follows acute middle-ear suppuration, which may mask the

presence of the complication. A remarkable case has been recorded by Dunbar Roy³ in which bilateral inflammation of the external auditory canal was followed by bilateral sinus thrombosis from direct extension to the mastoid emissary veins. There were no inflammatory changes whatever either in the middle ears or in the mastoid cells.

Perhaps insufficient importance has been attached to the mastoid emissary veins. Kieker⁴ has recorded a case of septic thrombosis of an exposed mastoid emissary vein secondary to a simple mastoid operation. Ligature and resection of the emissary vein cured this patient, and he regards this as a more common focus of infection than is generally supposed.

(d) Sinus thrombosis may be difficult to distinguish from or it may be accompanied by other intracranial complications. Numerous cases have been reported in which meningitis and especially cerebellar abscess have been associated with this condition, and I wish to refer here to the occurrence and significance of optic neuritis. Usually the fundus oculi is normal or shows merely some congestion of the retinal veins. Crockett, quoted by Kerrison,⁵ found optic neuritis in 25 per cent. of cases (in 15 out of 80). Kerrison states that this is a larger percentage than has been recorded by other observers. Milligan⁶ states that optic neuritis is present in nearly 40 per cent. of the cases. My own experience has been that it is at least as frequent as Crockett states and that it is not necessarily a sign of ill omen. The important point is that optic neuritis may occur without the presence of any other intracranial complication but septic thrombosis. It might be thought unnecessary to draw attention to this, but I have been present at a discussion by the bedside on this point by those who might have been expected to be better informed. The patient in this instance recovered after the sinus had been opened and the jugular ligatured.

The swelling of the optic disc almost always subsides, but Friedenwald and Downey⁷ have reported a case in which a subtemporal decompression became necessary on account of persistent choked disc following lateral sinus thrombosis with progressive failure of vision. They refer also to another case from a German source. The necessity for this must be very uncommon, because lumbar puncture would usually give relief to a coexistent serous meningitis.

Difficulties in Determining the Condition of the Exposed Sinus.

If the wall of the lateral sinus is found to be sloughing there can be no doubt regarding the nature of the disease and the treatment required. The wall of the sinns may, however, be found covered with granulations forming the boundary of a perisinous abscess, or it may be apparently normal. In these circumstances Professor Moure⁸ attaches great importance to pulsation in the sinns as an indication of the presence of a thrombus within. Granulations on the wall should be carefully searched for any tiny visible spot through which the infection may have reached the interior. If rigors have begun it is better to assume that an intravenous infection has commenced and act accordingly. If the symptoms are equivocal it is justifiable to wait. The following case illustrates this:

A boy, aged 7, had suffered from acute otitis media for a week. He was seen about 10.30 on a Thursday evening. The Schwartz operation was performed and revealed a perisinous abscess, the sinns wall being covered with granulations. As the pyrexia continued for thirty-six hours, although there was no rigor, on the following Saturday morning the sinus was opened and found full of septic clot. After this recovery was uninterrupted.

It is futile and dangerous to aspirate the sinus or puncture it with a hollow needle, since this proceeding cannot be relied upon to give any definite information, and it may well of itself induce a septic thrombosis by injuring the intima of a previously healthy sinus. Therefore it is better to do nothing or else deliberately incise the sinus. Aspiration of the sinus seems especially dangerous, since accidental injuries, though usually innocuous when properly dealt with, may lead to septic thrombosis. The following is an example:

A soldier, who was a driver in the Tank Corps, suffered from chronic otorrhoea on the right side. This caused him pain and headache, and he was unable to bear the noise and vibration of the machinery inside the tank. He agreed therefore to have a radical operation. It was found that the knee of the sinus lay so far forward that the posterior wall of the bony meatus was only one-sixteenth of an inch in thickness. I was at first inclined to abandon the operation; it was completed, however, by employing the method of Stacke, but the sinus was wounded before the end of the operation. The thrombus in the sinus afterwards became

in view which cannot be equally well attained by simply following the sigmoid sinus towards the bulb and dealing with the vein in the uock in this fashion. The indications for this operation have been so clearly stated by the same authority that I cannot do better than close these remarks with the following quotations from his writings:

"The view that operation on the vein is never required, and the view that operation on the vein is always required, are equally erroneous. It is as absurd to tie the vein for a local abscess, which should be dealt with in the sinus region as in other parts of the body by simple evacuation, as it is to deery all operations on the vein, when it may contain a spreading infective clot which has been known to reach the heart."¹²

"Operation on the vein should be undertaken (a) in acute praemia and septicaemia, whether the sinus is occupied by clot or by fluid blood; (b) if the sinus wall is gangrenous, or its contents are putrefying, unless it is perfectly clear that on both sides of the area of inflammation the sinus is completely blocked by non-infected thrombi (how seldom this qualification will be operative must be obvious to all who have had any considerable experience of these cases); (c) if it is proved or even suspected that the blood in the jugular bulb is in part or wholly clotted; and (d) if the jugular vein is thrombosed."¹³

DISCUSSION.

Mr. T. RITCHIE RODGER (Hull) said: It is difficult to estimate from a survey of the literature of the subject what proportion of cases of cavernous sinus thrombosis are an extension from a thrombosis in the sigmoid sinus and jugular bulb by way of the superior and inferior petrosals. Dwight and Germain concluded that 43 of their 182 collected cases were so caused; but as their review included the earliest cases reported details are wanting in many. In January, 1921, I reported four cases of cavernous sinus thrombosis to the Otolaryngological Section of the Royal Society of Medicine, of which cases one was an illustration of such extension, while in one other we were able to demonstrate a direct infection of the superior petrosal sinus by way of the small tympanic veins which drain into it. In this case rigors and extreme variations of temperature indicated a sinus thrombosis, and I exposed the sigmoid sinus accordingly. It appeared quite healthy, however, and I aspirated liquid blood from it, confining myself with ligation of the jugular vein till the blood removed should be examined. Pneumococci were reported to be present, and I presumed I was dealing with either a mural clot, not yet large enough to occlude the sinus, or a clot in the lateral sinus posterior to the point where the superior petrosal empties itself. Two days later I therefore opened the sigmoid sinus, which was now filled with clean red clot as a result of the ligation of the jugular, and when this had been scooped away, and the flow of blood from above established, two small worm-like pieces of grey-black clot were washed out, just of the calibre of the superior petrosal sinus. We presumed that the superior petrosal had been primarily infected, and that from that seat was being discharged into the blood stream the organisms which gave rise to the rigors and high temperature usually associated with sigmoid sinus thrombosis. The previous history of the case supported this, as the patient had giddiness and facial paralysis before admission, indicating infection of the petrosals. The other two cases were infected from in front—one from a facial carbuncle, the other from a frontal sinusitis. Since then I have had under my care two more cases, both of them illustrating infection from below, from an acute suppuration of the sphenoidal cell. Thus only in one case of six has there been extension of sepsis from the sigmoid sinus to the cavernous. The two cases last seen were almost identical in course and symptomatology, although different in onset.

CASE I.

A male, aged 29, was referred to my out-patient clinic by one of the general surgeons, with very large glands in the neck and below the lower jaw on the right side, the question being whether the obviously diseased tonsils might be the cause of the glandular

condition. He had also been referred to the dentist, who had earlier in the same day on which I saw him extracted twelve teeth. I advised removal of the tonsils, but recommended postponement till the mouth should have cleaned up somewhat. He was admitted under the surgeon's care, and I was again asked to see him three days later, as he had developed a purulent discharge from the right side of the nose and was running a high temperature. The right antrum was found to be full of pus, infection having occurred through a perforated tooth socket. Lavage by the nasal route having failed to produce any improvement, the intranasal antrum operation was performed. A week later severe frontal headache on the same side developed and a few days later the frontal sinus was quite dark on transillumination. The middle turbinal was amputated with the hope of establishing drainage, and the headache was at once improved and the temperature fell. He was discharged from the ward to come up as an out-patient, but failed to report for three weeks, when he came back looking very ill, with marked proptosis and oedema of the face. The radical frontal sinus operation was performed, no pus being present, but the mucous membrane was found to be gangrenous. The same condition obtained in the ethmoid cells, and from the antrum, which now communicated with the mouth by a large alveolar opening, the whole gangrenous mucosa was extracted in a mass by forceps. Death occurred after a few days. On post-mortem examination the antrum, ethmoid labyrinth, and frontal sinus were clean. The dura over the sella turcica was dark-coloured; the cavernous sinus on the left side was full of grey clot, that on the right was indistinguishable, the pituitary body and its surrounding structures forming a soft grey indefinite mass. The sphenoidal sinus was full of caseous material and its lining showed the same gangrenous condition as was found in the other sinuses operated upon. The extreme anterior tip of the temporo-sphenoidal lobe of the brain was discoloured greenish-grey and softened.

In this case, had we succeeded in clearing out the sphenoidal cell and its gangrenous lining with the same thoroughness as we finally attained in the case of the other sinuses involved, it is probable that the intracranial condition would not have ensued.

CASE II.

A female, aged 38. This case was very similar to Case I, except that the onset seemed to be due to an acute infective rhinitis. When first seen the patient had swelling of the right eyelids, with temperature 103° and tenderness over the right antral wall under the cheek. The right nasal fossa was completely blocked from general turgescence of the mucosa, and there was pus present. The left nasal fossa was normal. The left antrum and both frontals illuminated well, while the right antrum was completely dark. Several drachms of clear straw-coloured fluid were withdrawn from the latter on exploration. After a few days of unavailing conservative treatment the antrum was opened and the middle turbinal removed, the tissues being found necrotic. The general condition became gradually worse, and frontal sinus symptoms developed. The radical frontal sinus operation revealed the same gangrenous condition as in the other case. The eyes became more and more proptosed and immobile, and death ensued four weeks after the patient was first seen. Necropsy was not allowed, but there seems little doubt that this case was almost an exact parallel of the other.

Sir St. Clair Thomson has pointed out the probable frequency of this mode of infection of the cavernous sinus. When one thinks of the thin plate of bone, sometimes even wanting in parts, which forms alike the roof of the sphenoidal cell and the floor of the cavernous sinus—a bony plate certainly no thicker than that which separates the sigmoid sinus from the posterior mastoid cells—the possibility of extension of infection by erosion or by lymphatic or venous spread is apparent. Of course, the sphenoidal cell has a more or less efficient natural opening, an advantage denied to the posterior mastoid cells; and, moreover, infection of the sphenoidal cell is probably much less common than mastoiditis, hence the infrequency of one condition as compared with the other. Probably extension to the cavernous sinus from the cell beneath is more likely to occur in cases such as these two, where, all through, the accessory sinus infection was characterized by an acute gangrenous condition of the mucosa with very little formation of pus. Pus can escape from the ostium sphenoidale, but this opening is a very poor safeguard where the lining of the cell is gangrenous. Moreover, in these gangrenous cases bone erosion doubtless takes place readily. The antrum and ethmoid operations in both these cases gave one the impression of tearing through wet brown paper rather than bone.

Dr. HOLGER MYGIND (Copenhagen) said: I agree entirely with Sir William Milligan that the sigmoid sinus ought to be exposed and the interior explored in all doubtful cases. I would even go farther and say that if there is only the slightest doubt this exploratory operation ought to be performed. As far as the surgical treatment is concerned, at the first period of my surgical experience I was not very inclined to tie the internal jugular vein; then I saw several

cases where the ligature seemed to have stopped the progress of the disease and I applied the ligature very frequently. For the last five years I have, however, gone back to my old view and only use ligatures in cases where there is pus in the bulb, so that the upper part of the internal jugular vein may serve as a drainage tube. I do not go so far as to say that ligation is an injurious procedure, but my experience now is that it is generally useless, as will be seen from the 144 cases I have operated upon. Of these, 54 were treated with ligature, and of those 51.6 per cent. recovered, while amongst 90 treated without ligature 48.8 per cent. recovered, which practically shows no difference. My statistics also show that metastatic diseases of the lungs—the most fatal complications of sinus-phlebitis—occur in 27.7 per cent. of the cases treated without ligature and in 28 per cent. of those where ligature was applied. A very important factor as far as the prognosis is concerned is the question of whether the sinus phlebitis is complicated or not with other intracranial diseases, as the following statistics show:

	Total.	Recovered.
Sinus thrombosis (uncomplicated) ...	69	54 = 78.3%
Sinus thrombosis + meningitis ...	42	16 = 38.1%
Sinus thrombosis + subdural abscess ...	3	1 = 33.3%
Sinus thrombosis + brain abscess ...	2	0
Sinus thrombosis + brain abscess + meningitis ...	15	0
Sinus thrombosis + subdural abscess + meningitis ...	6	0
Sinus thrombosis + subdural abscess + meningitis + brain abscess ...	7	1 = 17.3%
Total ...	144	72 = 50.0%

Ago also is of very great importance as far as the prognosis is concerned, for in the period of from 20 to 29 years all cases of uncomplicated sinus thrombosis I have operated upon recovered, while from 30 to 39 years only 71 per cent. recovered, and the two patients over 50 years I have operated upon both died.

Dr. WM. HILL remarked on the want of uniformity in practice, not merely as regards tying the jugular vein, but also as to the extent of exposure and the exact clinical method of examining and exploring the sinus with a view to determining whether (1) the sinus wall was normal and its contents normal blood; or (2) there was clot, infected or otherwise; or (3) suppurating contents. It was desirable to remove enough bone to expose the sigmoid sinus for an inch. Palpation, seen and felt, might appear to be absent in an exposure of the size of a three-penny bit when obviously seen and felt in a larger exposure; this palpation rather pointed in favour of a normal condition of the wall and of contents. Where there was a doubt was it considered justifiable to insert a small hollow needle and aspirate and examine its contents? What precautions should be taken to prevent contaminating the sinus by the aspirating? Should not this preliminary aspiration precede slitting up the sinus, and should the exploratory incision in the first instance be a small one and then later enlarged if found diseased? The jugular vein was much less frequently dealt with in the neck than five-and-twenty years ago. If the thrombosis could be felt in the neck that was one indication for bringing the dissected upper portion of the vein out of the wound; also when it was certain that there was pus or a very septic clot in the jugular bulb.

Dr. DAN McKENZIE said that the diagnosis, particularly in the early stages of lateral sinus thrombosis, was frequently difficult, but the problem might be avoided by operating on the sinus on suspicion. This might be the more readily done, as exploratory operation was remarkably free from danger. The sinus should be exposed, freely opened up by a long incision, and, after arrest of bleeding, the interior of the vein carefully inspected. As regards the resection of the jugular vein in the neck, he always employed it when exploration of the sinus had revealed a clot. This step did not seriously add to the risk of the operation, and, in spite of opinions to the contrary, jugular resection did close the direct route between the lateral sinus and the general circulation. To this practice he had come, having been taught by fatal cases, which he attributed to the omission of this simple step.

Mr. FRANCIS MUECKE said that sinus thrombosis almost entirely prevailed among the poorer classes; it was in fact a disease of neglect. Only about 2 per cent. of the cases occurred in the better classes, and then generally they were of the acute streptococcal type. Among the symptoms he

pointed out the almost constant appearance of sordes about the gums and mouth, and herpes on the lips, and the false "general well-being" of the patient. He seldom saw the textbook symptoms of mastoid tenderness, swelling, and redness. The ordinary visible aural discharge frequently stopped some three or four months before the sinus symptoms appeared, but an aural examination would reveal a bead of pus sheltering small granulations. The mop on withdrawal would be found to have a peculiarly penetrating and disgusting odour; that part of the meatus close to the posterior edge of the drum would be red and granulating. Common mistakes in diagnosis were those of pneumonia, typhoid, or pyaemia of unknown origin, the absence of visible discharge having put the medical attendant off the scent. He was certain that a number of cases so called were not sinus thrombosis but rather meningo-phlebitis only, and would clear up entirely with the ordinary mastoid operation. He frequently found the sinus covered with profuse granulations and bathed in pus, and it was difficult to decide whether thrombosis was present. A simple method that he had found very efficacious was to push the sinus in with a blunt instrument, and if it sprang back quickly and evenly he left it alone, for even a thin parietal clot would prevent an even return. This method had seldom failed him. When clot was definitely present he plugged well above the clot and plugged the bulb if necessary. After eliminating the clot he freed the upper plug for a moment to give free flow. He always tied the jugular vein, for he knew of no way of being sure that some portion of clot would not escape. It seemed to him to be the only surgical procedure; it in no way added to the danger of the operation. There was no need to syringe through the vein or pull out the upper end. As a routine measure he gave four doses of 10 c.cm. of polyvalent antistreptococcal serum. Speed in operating he considered an essential feature of success owing to the toxic condition. As to the prognosis, 80 per cent. of cases uncomplicated by lung or cerebral conditions recovered. Pneumonia was a fatal complication—he only knew of one recovery. Joint complications were by no means unfavourable. Marked optic neuritis was seldom present—generally a slight dilatation of the vessels only. Blood tests were of little diagnostic value. Streptococci were more often found in the urine than in the blood. Following a mastoid operation sinus infection generally occurred about the tenth day. He believed dressing and antiseptics were more often the cause than operation injury. If he had cause to think sinus thrombosis present he operated as soon as he possibly could rather than wait for special tests to be done.

Sir JAMES DUNDAS-GRANT welcomed Professor Mygind's views in regard to ligature of the jugular vein, which agreed with his own expressed opinion. He would consider sordes (as pointed out by Mr. Muecke) of greater significance when associated with preservation of mental clearness. Sir William Milligan in his admirable exposition had referred to the rarity of sinus phlebitis in infants. This was explained by the great distance at which the sinus in infants was behind the mastoid. Macswen's line would in them lead to the cerebellum, as shown by some German investigations reproduced in Ballance's work on the temporal bone. The ligature of the vein was an important incident, but not the essential part of the operation, which was free exposure of the sinus, examination as to refilling after compression (refilling from below indicating absence of thrombotic obstruction of the bulb), and free incision. If (as often observed by Sir William Macswen) there was found a mass of broken-down purulent clot with healthy clot (or free normal haemorrhage) the broken-down portion might be cleared away without ligature of the jugular. If the jugular was ligatured it was imperative that the lower end of the upper part should be brought to the surface to permit of subsequent drainage. He had seen signs of danger persist until spontaneous extension of a ligature and escape of pus took place. He had opened the bulb (Gruntz's operation) on two occasions and recovery followed each time, but it was very rarely necessary to do this. A catheter might be passed up the jugular vein to the dome of the bulb and suction exercised by means of a syringe. Koerner recommended, a number of years ago, for the treatment of cavernous sinus thrombosis the encouragement of ment of cavernous sinus thrombosis the encouragement of free haemorrhage from the lateral sinuses in hope of bringing away the clot.

Dr. ANDREW WYLIE remarked that there was very little to say after such excellent papers had been read on the subject, but he might mention that most of his cases had been

females. Hunter Tod in 1919 demonstrated that such complications developed on the tenth day, and therefore no mastoid case should be allowed out of bed until after that time. They were all agreed that no needles or syringes should be used; the sinus should be freely opened, and if the temperature did not drop and the case was one of pure septicaemia, then into one of the veins in the arm 20 ccm. of 1 in 2,000 solution of corrosive sublimate should be injected. This would cure the case unless a septic embolus was present. Mr. Colledge remarked that malaria and septic sinus conditions had been complicated, and he (Dr. Wyllie) remembered once opening a sinus which was quite healthy, the rigor and fever having been caused by malaria. There was sometimes also a difficulty, in cases where a suppuration in both ears was present, to know which to open when symptoms of sinus infection appeared. The eye symptom must be relied upon in such cases. He did not ligature the jugular in the first place, merely opening the sinus freely, but if there was no improvement, then a more thorough operation should be performed and the vein ligatured.

Dr. W. S. SYME (Glasgow) said that spontaneous cures of lateral sinus thrombosis might result was exemplified by a case which came under his care. A woman, following the birth of a child, developed what was thought to be puerperal septicaemia, and she was treated accordingly, and after some time recovered. Several years later he performed a radical mastoid operation on her for otorrhoea of many years' duration. The sigmoid sinus was extensively exposed by the disease and was found to be completely converted into a firm fibrous band.

Dr. DOUGLAS GUTHRIE (Edinburgh) described a case in which removal of an aural polypus was followed by sigmoid sinus thrombosis. The earliest symptom was pain on swallowing in the region of the tonsil on the affected side. He was unaware of any mention of this symptom in cases recorded in literature. Another interesting phenomenon which was noted in the above case was that the profuse perspiration was unilateral. It was confined to the side of the lesion and affected the side of the head and neck and also the arm. This continued for several days after the temperature, as a result of operation, had subsided, and was unaccompanied by any other signs, such as dilatation of the pupil, suggesting a lesion of the sympathetic system.

The President, Dr. A. A. GRAY, drew attention to the importance of not injuring the sinus in ordinary mastoid operations. It was possible that highly penetrating antiseptics—for example, eusol—might cause thrombosis in an exposed sinus.

BENIGN FORMS OF OTOGENIC MENINGITIS.

BY
HOLGER MYGIND, C.B.E., M.D.,
COPENHAGEN.

[Abstract.]

This paper is based upon the observation of 210 cases of otogenic meningitis of all forms treated in the ear and throat department of the Copenhagen Commune Hospital during the last seventeen years. These cases were divided according to age and the number of recoveries in the following way:

Under 1 year 6, of whom 1 recovered = 16.6 per cent.		
1-4 years 12	1	= 8.3 "
5-14 " 61	26	= 42.6 "
15-19 " 23	8	= 35.0 "
20-29 " 34	10	= 30.0 "
30-39 " 27	5	= 33.0 "
40-49 " 15	3	= 22.0 "
50 years and over 32	2	= 6.2 "
All ages 210	59	28.0 "

If the material is divided into groups as the meningitis was either uncomplicated or associated with other important intracranial diseases, the number of recoveries is as follows:

	Cases.	Recoveries.
Meningitis (uncomplicated) ...	115	38 = 33.0 per cent.
Meningitis + sinus-phlebitis ...	42	16 = 38.1 "
Meningitis + brain abscess ...	21	4 = 19.0 "
Meningitis + subdural abscess ...	2	0 = 0.0 "
Meningitis + brain abscess + sinus-phlebitis ...	2	0 = 0.0 "
Meningitis + brain abscess + sinus-phlebitis ...	15	0 = 0.0 "
Meningitis + subdural abscess ...	6	0 = 0.0 "
Meningitis + sinus-phlebitis + subdural abscess + brain abscess ...	7	1 = 14.2 "
Total ...	210	59 = 28.0

Chronic suppuration of the middle ear was decidedly more frequently the cause of benign meningitis than of malignant. Streptococcus infection was predominant in the benign cases, while pneumococcus infection played a comparatively important part in malignant cases.

The benign forms of otogenic meningitis do not, however, appear only amongst patients who recover. In a series of cases of meningitis complicated with other intracranial diseases which ended in death, the meningitis was seen to disappear before death after having presented distinct objective meningitic symptoms.

Pathological Definition of Meningitis.

The usual definition of meningitis as a diffuse inflammation of the leptomeninges with the formation of a purulent exudate in the subarachnoid spaces does not hold good in all cases, and the author quotes several examples of this from his own experience. Examples are especially quoted of cases where the cerebro-spinal fluid was distinctly meningitic, and where the macroscopical examination *post mortem* showed no exudate or other signs of inflammation of the leptomeninges, while the microscopical examination revealed the existence of inflammation of the leptomeninges. The paramount significance of lumbar puncture is emphasized.

Clinical Definition of Meningitis.

Based upon experience with about 2,000 lumbar punctures, the author gives a synopsis of the different characteristic features of the cerebro-spinal fluid in meningitis, and draws up two forms, from which there are, however, many exceptions:

	Cerebro-spinal Fluid.	
	Malignant.	Benign.
Appearance ...	Turbid.	Clear or opalescent.
Type of pleocytosis ...	Polynuclear.	Mononuclear.
Bacteria ...	Present.	Absent.
Pressure ...	Very high.	Moderately high.

As to the number of cells which constitutes a pleocytosis, the author has come to the conclusion that if there are three or more cells in each cubic millimetre, and if there are diffuse brain symptoms, meningitis is sure to be present. Three to fifteen cells must be considered as slight pleocytosis; 15 to 150-200 does not generally make the cerebro-spinal fluid turbid, and can be considered as moderate; while a number exceeding these figures must be considered as high pleocytosis.

Using lumbar puncture as a diagnostic means the author defines otogenic meningitis from a clinical point of view as an acute febrile brain disease, caused directly or indirectly by an acute or chronic middle-ear suppuration, exhibiting diffuse brain symptoms and a cerebro-spinal fluid with pleocytosis.

Lumbar Puncture not Infallible.

In this part of the paper the author deals with the exceptional cases, where there is a distinct contradiction between the benign character of the cerebro-spinal fluid emptied by lumbar puncture and the grave state of the patient. Three cases are especially mentioned of fatal uncomplicated meningitis where the cerebro-spinal fluid assumed a benign character *sub finem vitae*; in each case considerable plastic and thick exudates were found on the base of the brain at the post-mortem examination. In such cases it is easy to understand that the free connexion of the cerebral fluid with the spinal fluid has been interrupted, and the lumbar puncture principally indicates the state of the leptomeninges in the spinal canal.

Benign Uncomplicated Meningitis with Turbid Cerebro-spinal Fluid ("Benign Purulent Meningitis").

This group consisted of 22 cases, which all recovered. The average age was 23.6 years, the oldest 50, the youngest 2 years of age.

In all except one polynuclear cells were present in the cerebro-spinal fluid, predominating in 16 cases, while in 4 an equal number of both was present, and in 2 an excess of mononuclear cells. Bacteria were present only 4 times.

The initial symptom was generally vomiting, sometimes shivering. The temperature was never normal, but was in

a few cases only slightly raised, while in one-third of the cases it was 104° and beyond. Drowsiness was a very prominent symptom: deep sopor appeared twice. Rigidity of the neck was generally present, and so was Kernig's sign, while Babinski's sign only appeared five times. Optic neuritis was observed seven times. In one case a piece of the brain was removed for microscopical examination, which revealed the existence of a considerable acute leptomeningitis with fibrinous exudates on the surface (but no encephalitis as expected).

All these cases ended with complete recovery after operation, but in one case concerning a child aged 2 operation was refused and the child still recovered. This very rare and remarkable case shows that there may be a tendency to spontaneous recovery in some forms of otogenic meningitis.

Benign Uncomplicated Meningitis with Clear Cerebro-spinal Fluid ("Collateral Meningitis").

The 16 patients belonging to this group all recovered after they had been operated. They were on an average 20 years old, the oldest being 50 years old, the youngest 20 months.

The number of cells in the cerebro-spinal fluid varied from 3 to 198 per cubic millimetre; eight times only were mononuclear cells present; five times there was an excess of these, and three times an excess of polynuclear cells. In no case were bacteria found. The pressure was normal only twice, generally it was 300 to 500 mm., but in one case it rose to 950 mm.

The temperature was normal only twice; in the majority of cases it was slightly raised, and in five it was about 104° . Also within this group vomiting was frequently the initial symptom, and often appeared later in the course of the disease, even when the patient otherwise did well. Drowsiness is also an important symptom, though often slight and easily overlooked. Rigidity of the neck appeared eleven times, Kernig's sign only five times, while Babinski's sign was present six times. Five patients had optic neuritis; paresis of the abducent nerve appeared twice. The recovery often took a long time, the pleocytosis frequently disappearing very slowly.

As the true nature of this form of meningitis may be doubtful, the author proposes to call it "collateral meningitis," this name involving a distinct interpretation neither of the character nor the extension of the inflammatory process of the leptomeninges. Further, "collateral meningitis" expresses the dependence of the process upon a primary focus and also its tendency, like other collateral inflammations, to recede when the primary focus disappears.

Benign Meningitis in Cases of Sinus-phlebitis.

This group embraces 16 cases of recovery, of which 8 exhibited clear and 8 turbid cerebro-spinal fluid. The predominant formulae were polynuclear. Bacteria were only found once. They all recovered completely, but one patient died a year after from uncomplicated meningitis originating from the other ear. The brain symptoms were often covered by the symptoms of the phlebitis.

In one case with slightly turbid cerebro-spinal fluid, microscopical examination of a piece of brain tissue extirpated during operation revealed the existence of considerable inflammation of the leptomeninges of the cerebellum. In several cases where there was a combination of sinus-phlebitis, which terminated fatally, and meningitis, the latter showed a benign character, being either very slight or disappearing entirely before death. In two cases of collateral meningitis as complication of lethal sinus-phlebitis, the post-mortem examination showed no macroscopical signs of leptomeningitis, while the microscope revealed the existence of this complication.

Benign Meningitis in Cases of Brain Abscess.

The cerebro-spinal fluid obtained by lumbar puncture was generally of a benign character. The principal feature of the cerebro-spinal fluid is, however, that it changes from one lumbar puncture to another, being now clear and now turbid, now containing principally polynuclear cells, and at another lumbar puncture mononuclear cells principally, etc. Whether uncomplicated brain abscess may give a meningitic cerebro-spinal fluid by lumbar puncture must still be *sub judice*.

Operative Measures.

The most important factor is, of course, the early elimination of the primary focus, whether this is in the middle ear alone or also in the petrous bone, the labyrinth, etc.

But in many cases even an operation performed as early as possible is not able to avert the fatal course of the disease. There seem to be really two forms of otogenic meningitis. In the one, and by far the most frequent, the inflammatory process in the leptomeninges spreads like the explosion of a barrel of gunpowder ignited by a spark, and any operation is useless. In a minority of cases, say one-third, the spark—that is, the inflammatory products from a primary focus—is not able to cause the explosion before the fire has been nourished for some time from the focus, such cases the latter is eliminated, the further feeding of inflammatory products ceases, and the nascent inflammation of the leptomeninges recedes.

This idea has been the author's principal guide during the last decade in operative treatment of otogenic meningitis. For seven years previously all sorts of supplementary operations were tried. The author now considers them not only useless but even as injurious, and the results seem to be better now.

As, however, craniotomy involves no danger when the dura mater is not opened, this operation is to be recommended to enable the operator to examine the dura minutely. If the menbrano shows no sign of a deeper-going disease, the author now always makes a halt here, when there is suspicion of subdural or cerebral abscess.

Formerly the author always performed "radical mastoid operation" also in acute cases in order to examine the labyrinth minutely; now only simple mastoid operation is performed in acute cases, as we nowadays possess means of accurately testing the function of the labyrinth.

Repeated lumbar punctures the author considers not only useful as means of following the decrease or increase of the meningeal process, but also beneficial, especially when the pressure of the cerebro-spinal fluid is very high or the patient is suffering from severe headache or nausea.

DISCUSSION.

Mr. FRANKS MUECKE had always looked on acute meningitis as an almost fatal condition, and was surprised at the author's excellent statistics. He would like to mention a method he used lately in a case of meningitis with advanced symptoms. He inserted a tiny gauze wick through a very small hole in the dura above the tegmen antri and another behind the sinus into the posterior fossa, changing them every day for four days, when all meningeal symptoms had disappeared and an ordinary mastoid recovery took place. He only mentions this so that others might try it if they wished and see whether this case were a lucky-chance or not.

Dr. W. S. SYME had three cases of recovery from what was generally called purulent meningitis. In two this result followed transabyrinthine drainage. In both the cerebro-spinal fluid was very turbid, but no organisms were found nor did any grow. These two cases might be classed as serious meningitis, though it seemed difficult to imagine the so turbid a condition of the spinal fluid could be found in this condition. The third case was more difficult to understand. This case recovered after repeated lumbar puncture. In the fluid organisms were found, but these did not grow. It seemed to him that in that case a definite bacterial meningitis had to be dealt with which recovered. From that case seemed to follow that, treated early, it was possible for a case of definite purulent otogenous meningitis to recover.

Mr. T. RICHARD RODGER said that Professor Mygind had succeeded in producing a very different atmosphere from that of the Newcastle discussion on the same subject last year. There the discussion resolved itself into that of the different methods of draining the meninges, and the impression conveyed was that the sooner this was done the better, if meningeal symptoms were present at all. Professor Mygind, however, recognized that evacuation of the primary focus in the antrum or middle ear might be followed by rapid recession of the symptoms of meningeal irritation. This could be easily understood if we thought how frequently we found acute mastoid cases with tenderness and oedema over the mastoid process, and oedema of the superficial mastoid cells, but not pus till the antrum was reached. If a drop of pus in the antrum could produce such marked collateral symptoms, at a distance of an inch on its superficial aspect, what was to be expected on the far side of the tegmen antri? Was it not likely that there oedema and serous effusions could be produced, designed by nature for protective purposes, but capable

in certain cases of producing symptoms of irritation, even of pressure? He had had two such cases where draining of the mastoid antrum was followed in a few hours by clearing up of the meningeal symptoms, and both of these cases showed the Kernig and Babinski signs confined to the opposite side of the body, a restriction to which Professor Mygind had referred as occurring in some cases.

IS IT WORTH WHILE TO REMOVE AURAL POLYPI?

BY

J. S. FRASER, M.B., F.R.C.S.,

Surgeon, Ear and Throat Department, Royal Infirmary, Edinburgh;

AND

STEPHEN YOUNG, M.B., Ch.B.,

Senior Non-Resident House-Surgeon, Ear and Throat Department, Royal Infirmary, Edinburgh.

This paper is based mainly on the results obtained by the removal of aural polypi during the period 1915 to 1921 at the Ear and Throat Department of Edinburgh Royal Infirmary, under the charge of Dr. Logan Turner.* It should be stated that during the years 1907 to 1910 aural polypi were, as a rule, removed in the out-patient department by means of the cold wire snare, and thereafter the patient was instructed to carry out the usual conservative treatment of chronic middle-ear suppuration by means of syringing and the use of spirit drops. The results were not satisfactory, as in almost all cases the polypus returned. It was therefore at this time considered useless to continue treatment on these lines, and accordingly patients suffering from chronic middle-ear suppuration with aural polyps were, as a rule, advised to submit to the radical mastoid operation. It was found, however, during this operation that in some cases there was little or no disease in the mastoid antrum and that the malleus and incus were healthy. As a result of this finding it was determined to give a further trial to removal of aural polypus through the external meatus. (It is important to note that the term "aural polypus" is used to indicate only cases in which there is a definite projecting polypoid growth. Cases in which a large perforation was present and the inner wall of the tympanic cavity was seen to be covered by red "granulations" are not included.) Removal of the polypus allows the surgeon to see the site of the perforation in the drumhead and the type of middle-ear suppuration present. If the perforation is central, then we may hope for a cure of the suppuration by means of conservative treatment after removal of the polypus. If, on the other hand, the perforation is marginal or in Shrapnell's membrane, then we cannot expect a good result from removal of the polypus alone.

Technique of Removal.

The methods employed in the removal of aural polypi can be divided into two groups: (1) In the early cases of the present series Neumann's local anaesthesia was employed alone, and the polypus was removed with the cold wire snare and ring knife. (2) Later, a general anaesthetic (ethyl chloride) was employed in addition to Neumann's local anaesthesia, and the stump of the polypus was canterized by means of a chromic acid bead. After removal of the growth the ear was treated daily, first of all with hydrogen peroxide drops; secondly, by syringing with a dilute solution of lysol (half a teaspoonful to the pint of lukewarm water); thirdly, by drying out the meatus with cotton mops; and, lastly, by the instillation of boric acid in rectified spirit. Before the polypus was removed, the cochlear and vestibular apparatus were tested to make sure that the inner ear was healthy and that no symptom of fistula was present.

During the years 1915 to 1921 there attended the Ear and Throat Department of the Edinburgh Royal Infirmary 2,072 cases of unilateral and 685 cases of bilateral chronic suppurative otitis media, giving a total of 3,442 suppurating middle ears. In 102 of these cases aural polypi were removed.

We have attempted to find out the frequency of aural polypus in chronic middle-ear suppuration, and for this purpose have taken the period 1915 to 1917 (inclusive), during which 1,430 chronic suppurating middle ears were investigated at the department. Of these, 311 showed aural polypi—that is, 22 per cent.

* The writers are indebted to Dr. Logan Turner for permission to publish the results.

Results Obtained by Removal.

Of the 102 cases in which the aural polypus was removed 70 reported after a period sufficient to enable us to say whether the operation had been successful. The results of removal may be classified into three more or less distinct groups: (a) those in which the removal of the polypus, followed by conservative treatment, resulted in cure—that is, cessation of discharge and non-recurrence of the polypus—15 cases, or 22 per cent.; (b) those in which there was no recurrence of the polypus but in which the ear continued to discharge in spite of conservative measures—15 cases, or 22 per cent.; (c) those in which there was continued discharge from the ear, associated with recurrence of the aural polypus—38 cases, or 54 per cent.; (d) there were two deaths. These are dealt with later.

Site of Origin of the Polypus.

Korison states that, while occasionally springing from the promontory, this site is exceedingly rare as compared with the outer wall of the vault or the diseased inner end of the bony meatus. McBride, Hunter Tod, Politzer, Gleason, Barr, and others agree, on the whole, that the commonest site of origin is some part of the inner wall of the tympanic cavity. In a previously published report on the radical mastoid operation (*Journal of Laryngology*, 1919, vol. xxxiv, p. 373) one of us (J. S. F.), in conjunction with Dr. Garretson of Detroit, U.S.A., stated that of 156 cases in which the condition of the tympanum was noted at the time of operation, in 69 there was a polypus growing from the promontory and in three from the attic.

Of the 102 cases of the present series in which an aural polypus was removed 31 came eventually to the radical mastoid operation. As far as could be ascertained, the site of origin of the polypus in these cases was as follows: inner wall of tympanum, 16; attic, 2; doubtful, 13. The 13 cases where the site of origin could not be stated definitely belonged to the group in which the aural discharge continued without the recurrence of the polypus. In 9 of the 31 cases which came to the radical mastoid operation cholesteatoma was found in the middle-ear spaces at operation.

Dangers Associated with Aural Polypi.

(a) *Danger of Mastoid and Intracranial Complications.*—Packard and others have stated that obstruction by aural polypi to the escape of discharge increases the risk of mastoid and intracranial complications in chronic suppurative otitis media. In the report by Fraser and Garretson (mentioned above) it was noted that the tympanic membrane was obscured by a polypus in 129 out of 248 cases of chronic middle-ear suppuration in which the mastoid operation was performed. Further, an aural polypus was present in 8 out of the 25 cases of intracranial complication, and in 21 out of 26 cases with labyrinthitis recorded in the paper. There seems to be little doubt, then, that the presence of an aural polypus in a case of chronic middle-ear disease is at least a predisposing cause of mastoid, labyrinthine, and intracranial complications.

(b) *Danger Connected with Removal of Aural Polypi.*—In two of the 102 cases recorded above removal of the polypus was followed by the death of the patient. The clinical records of these two cases are as follows:

CASE I.

D. R., male aged 58, was first seen on February 16th, 1913, suffering from chronic suppurative otitis media (bilateral). Both drumheads were obscured by large polypi. With the noise apparatus in the left ear the raised voice was heard close to the right ear; hearing in left ear similar. On February 20th, under Neumann's local anaesthesia and general anaesthesia by ethyl chloride, polypi were removed from both ears. The patient became restless when recovering from the anaesthetic. At 3.30 p.m. he became unconscious, with paresis of the left side. He died the next day.

Post-mortem Examination.—Atheroma of the cerebral arteries. There was a large haemorrhage into the basal ganglia on the right side of the brain. Death in this case was not directly associated with the removal of the aural polypi but with the atheroma of the cerebral arteries.

CASE II.

J. M., female aged 27, was first seen on June 6th, 1919, suffering from chronic suppurative otitis media (right) with polypus. With noise box in left ear the raised voice was heard at one foot. Rotation both to right and to left produced after-nystagmus of twenty seconds' duration. On July 3rd a polypus was removed from the right ear. The next day the patient was well and was discharged. On her return home she developed a rash (diagnosed as scarlet fever) and died within a short time. She had no sore throat at the time of admission, but was apparently operated on during the incubation period of scarlet fever.

A third case, although it did not occur during the period under examination, is so thick of sufficient interest to deserve mention. The record has been previously published in the *Proceedings of the Royal Society of Medicine*, 1916, vol. ix (Otolological Section), p. 75.

CASE III.

C. G., female aged 6, had discharge from the left ear following an attack of measles at the age of 3 years. On December 25th, 1911, she had severe pain in the left ear, followed by vomiting, dizziness, and headache. (This was probably an attack of labyrinthitis.) The symptoms gradually improved, and by January 8th, 1912, she was fairly well. When seen for the first time, on January 13th, the left external meatus contained pus and polypoid granulations. There was no mastoid tenderness. The tonsils were enlarged and a mass of adenoids was present. Adenoids and tonsils were removed on January 15th. Unfortunately, at the same time the granulations in the left ear were also curetted, a procedure which should be strictly avoided unless the labyrinthine function has been tested and found normal. On January 17th, 1912, the patient was cyanosed and vomiting; temperature 103.2°F , pulse 160. Next day complete deafness was noted in the left ear; giddiness was present; there was rotatory and horizontal nystagmus to the sound side (right). The pulse was feeble, the tongue furred, diarrhoea present. The cerebro-spinal fluid was under increased tension but clear; films showed streptococci and bacilli. Operation was considered hopeless. On January 19th antistreptococcus serum was given; facial paralysis was noted on the left side, and death ensued.

Post-mortem Examination.—Cloudy swelling of kidneys, heart, and liver; petechial haemorrhages in lungs; the mesenteric glands showed recent acute inflammation in addition to chronic enlargement. No obvious meningitis. The appearances were those of acute septicaemia.

The case appears to have been one of septicaemia and malignant serous meningitis following removal of tonsils and adenoids and curettage of ear granulations in a patient suffering from latent labyrinth suppuration. Microscopic examination of the left ear confirmed the presence of labyrinthitis.

Conclusion.

In a case of chronic middle ear suppuration, with aural polypus, if (1) there are no acute symptoms (otache, headache, mastoid tenderness, dizziness, vomiting, shivering, etc.), (2) the labyrinth is found to be healthy on examination, and (3) it is possible to have efficient conservative treatment, we hold that it is advisable to remove the polypus through the external meatus in the first instance. If the growth recurs after efficient removal followed by careful after-treatment, the radical mastoid operation is called for.

DISCUSSION.

Dr. HOLGER MYRIND said that he had had a few unpleasant experiences connected with the removal of polypus of the ear. In one case a facial paralysis occurred at once after the removal, and in two other cases labyrinthitis with loss of hearing appeared directly after the operation. He did not think, however, that such cases should prevent surgeons from removing polypi; he always did it in cases where it was not a polypus recurring after having been removed by a competent specialist; in such cases radical operation was to be recommended.

Sir JAMES DUNDAS GRANT said that as a matter of routine he insisted on the instillation of drops of zinc chlorido and alcohol for a week before the removal of a polypus when it was bathed in pus. He recalled a case in which, after the removal of what seemed to be a granulation polypus, the symptoms of an existing cerebellar abscess developed. For the examination of the labyrinth he recommended the case of his own "cold-air" apparatus. The removal of polypi was decidedly important.

Sir WILLIAM MILLIGAN attached great importance to antiseptic treatment of the meatus and middle ear for a week before the removal of an aural polypus.

Dr. J. S. FRASER, in reply, said: I agree with the President that it is very difficult to state with accuracy the site of origin of the aural polypus in many cases. With regard to the danger of removal of the polypus, I can only say that I have, fortunately, not met with any cases of facial paralysis of uncontrollable bleeding as a result of this small operation. I fail to understand the stress Sir William Milligan lays on the importance of antiseptic treatment before removal. In a great many cases the polypus is really acting as a tight cork in the external meatus, and I do not see how one is going to render antiseptic the inner end of the meatus,

much less the tympanic cavity and other parts of the middle ear cleft. I am glad that most of the speakers agree that it is advisable to remove polypi in uncomplicated cases; just as every dog is allowed one free bite, so I think an aural polypus may be allowed one removal, granted that the labyrinth is healthy and that there are no acute symptoms.

SECTION OF LARYNGOLOGY.

JOHN MACINTYRE, M.B., C.M., F.R.F.P.S., President.

DISCUSSION ON DISEASES OF THE OESOPHAGUS, THEIR SYMPTOMATOLOGY AND DIFFERENTIAL DIAGNOSIS.

OPENING PAPERS.

I.—AFFECTIONS OF THE SUPERIOR OPENING OF THE OESOPHAGUS.

BY

D. R. PATERSON, M.D., C.M.,

JC.

Surgeon, Ear and Throat Department, King Edward VII Hospital, Cardiff.

My first and pleasing duty is to express my thanks for the honour you have done me in asking me to open this discussion. At the London meeting of the Association in 1910 I had the privilege of taking part in introducing a discussion in this Section on the technique of the direct examination of the oesophagus, then in its earlier stages. Since that time a great deal of work has been done on the subject of oesophageal disease in which members of this Section have taken a conspicuous part, and it is perhaps not inappropriate to-day to indicate in a short survey some of our advances and some of the problems which still await solution. For this purpose it has been thought desirable to approach it from the clinical side with a view to making an attempt to assess the value of symptoms as they appear to the practitioner in his daily work. In discharging the duty laid upon Mr. Howarth and myself we have thought it might be of advantage if I confined myself mainly to affections of the superior opening of the gullet whilst he dealt with those of the lower segment. This is not an ideal division, but it has certain practical advantages, as each section presents some special features of its own. It will be understood, therefore, that the following remarks are concerned chiefly with the upper orifice.

The semeiology of oesophageal disease is comparatively simple. What may be termed the oesophageal syndrome consists essentially of two main parts in the mechanism of deglutition, the maximum effect of the movement being produced where the sphincter fibres are most developed—namely, at the entrance and at the lower end. It is, however, a canal of transmission, and anything which interferes with the movement of food may produce difficulty of swallowing or dysphagia. This is a condition common to all diseased states of the gullet, and is generally the initial symptom. Its onset may be gradual, commencing with difficulty in passing solids, extending later to semi-solids, then liquids, and finally, it may be, to complete inability to swallow. Where the seat of obstruction is high up at the orifice of the canal, fits of coughing are apt to accompany the attempt to swallow from food finding its way into the air passage, making the patient nervous and disinclined to eat, except in small quantities. On the other hand, the appearance of dysphagia is sometimes sudden and often related to spasm. This may be transitory and very variable, appearing and disappearing suddenly, though in cases where it is well established it may become more or less permanent. Dysphagia may thus be due to organic obstruction or to spasm at the superior opening, or to a combination of both; for it is not unusual—for example, in early malignant disease—to find an element of spasm which is largely responsible for the dysphagia. Its onset in a hitherto healthy person is always important and its significance should not be overlooked. In certain general states—for example, where there is pronounced anorexia—there may be disinclination, amounting to declared inability, to swallow, and a somewhat similar condition may likewise be met with in certain neurotic states, but as a rule there is not much difficulty in their differentiation. On the other hand, where dysphagia is not very pronounced and attention is monopolized by the presence

of a prominent external swelling such as enlarged cervical glands or infiltration of the thyroid, its presence may be overlooked, and instances are not unknown where such secondary glands have been removed and the thyroid operated on in ignorance of the primary disease in the gullet—a diagnostic pitfall, one need hardly say, to be avoided. It must of course be borne in mind that difficulty of swallowing may be due to other affections, such as post-diphtheritic and bulbar paralyses, retropharyngeal abscess, tuberculous and malignant disease of the larynx, cicatricial malignant obstruction of the hypopharynx, even to pressure by external tumours; their differentiation, however, does not as a rule remain long in doubt.

Regurgitation of food may be a sign of considerable value. If it takes place at once and the food returns unaltered, it points to the seat of obstruction being high up. The regurgitation of fragments of food undigested, after several hours or days, is of course diagnostic of a pharyngeal or pressure pouch.

Of the symptoms of less value, painful sensations, such as burning in the region of the larynx, a feeling of tension or constriction, etc., are not uncommon. More significant is more or less continuous pain, increased by swallowing, in the region of the cricoid—a symptom often associated with malignant disease. With it there may be pain in the ear, often distressing and difficult to relieve, and probably to be explained by the intimate relations of the facial and glossopharyngeal nerves. When this occurs in dysphagia of long standing it too often indicates the superintention of grave disease in the lower pharynx or cricoid region.

Salivation sometimes attracts attention. It may be reflex from a traumatic lesion around the introitus, or due to great obstruction there, as by the impaction of a foreign body. In well-established malignant disease it may be profuse and productive of great discomfort. The clinical picture of a patient mopping the saliva from the lips with a towel is familiar to most of us. A most distressing instance of this nature which came under my own notice was a young married lady, six months pregnant with her first child, and suffering from advanced malignant disease in the post-cricoid region.

Of the physical examination in such cases I need say but little. Careful palpation of the neck and the region of the larynx should be carried out. Internal palpation is often of great value, for it ought not to be forgotten that disease in the hypopharynx is within reach of the finger. The laryngeal mirror is indispensable in ascertaining the presence or absence of disease in the post-cricoid region and should always be made use of in the first instance. In many cases it may establish the diagnosis at once. With its aid the upper margin of a growth may be visible. The advantages of radiography are well known to you. The fluorescent screen is invaluable in the preliminary examination. With the patient in the oblique position—that is, with the head and upper part of the body turned half-way to the left and the right shoulder in contact with the screen—the dense shadows of the spine and of the heart and aorta are displaced and a good picture of the bismuth meal obtained. We can get a clear and distinct view of the hypopharynx and much useful information of the way in which the bolus behaves at the mouth of the gullet. Even a new growth may be outlined by the small particles of bismuth arrested in its fissures and erosions. I need hardly emphasize the value of an x-ray installation as a normal adjunct to a modern throat clinic. Some Continental hospitals are already ahead of us in this.

As a diagnostic means the use of the bougie in a blind fashion is not to be recommended. Its value is not great, it tells us much less than other more accurate methods, and it is not without danger in certain states. Personally I always like to reconnoitre well the local condition before using the bougie for the purposes of treatment.

On the value of endoscopy it is unnecessary to enlarge. It is now well established as a routine method in the examination of the oesophagus. We know its advantages and its limitations, and as a specialty it is permissible to congratulate ourselves and claim some measure of credit for making an important contribution to practical medicine. Its later development—suspension laryngoscopy—is especially adapted for investigation of the post-cricoid region.

If we now consider shortly some of the more important affections of which the above symptoms are an outward expression, it would be well to remember that the element of spasm plays an important part in many morbid conditions of the gullet. It runs through all its pathology, though there has perhaps been a tendency to exaggerate it as a primary

condition. Symptomatic spasm we are familiar with in such general states as hydrophobia, tetanus, and in certain poisons. The endoscope has taught us that a spasmodic stricture of the upper opening may be secondary to a small local lesion such as an ulcer or the impaction of a fish bone. It may even have a more distant cause, and I have had the experience, like some of my colleagues, of regarding a spasm at the cricoid opening as primary and overlooking for a time the presence of graver disease at the lower end of the canal of which it was but a reflex expression. Spasm may thus be the outcome of a simple or a serious lesion, though the resulting dysphagia may be equally marked in both.

Of the group of spasmodic dysphagias in which no local exciting cause can be made out, those of a more or less temporary character are not infrequent. They occur chiefly in young people, generally of the female sex. Their onset is usually sudden, often accompanied by choking attacks, and they usually pass off equally rapidly. Dysphagia is rarely complete and usually limited to solids. Emotional states are often the exciting cause, and it is commonly regarded as a manifestation of hysteria. The fluorescent screen may show a little holding up of the meal which the endoscopic tube shows to be due to a certain degree of spasm at the mouth of the gullet.

Of greater importance are cases where spasm at the upper opening occurs in women, usually about middle age. Dysphagia here is prominent, and may be the only symptom for years until loss of weight, anaemia, characterized by diminution of haemoglobin, and poor health set in. A long history is frequent and characteristic; it may date from ten, fifteen, or even thirty years. The patient has "a small swallow," she takes progressively longer at meals until it becomes a social disability. The passage of a tube may relieve it for a time, but it often gradually returns. Occasionally its beginning may be sudden—for example, in several cases under my own care it came on after a complication of childbirth, such as severe flooding. As a rule the patient has no doubt as to the seat of obstruction, which she refers to the region of the larynx. A certain degree of variation in the dysphagia may be noted; swallowing may improve for a time, only to be affected again by an intercurrent illness. This variation is apt to deceive the practitioner, who regards the patient as fauciful, and leads him to make a diagnosis of hysteria, for which there is rarely justification.

On a former occasion I dwell on its not infrequent association with changes in the buccal and pharyngeal mucosa. From the smooth glossy upper surface of the tongue with whitish patches, and a tendency to dryness in advanced cases, it has been termed chronic glossitis, but it is important to note that this change is by no means confined to that organ, as the mucosa of the mouth, pharynx, and even the upper section of the oesophagus is likewise nearly always involved. This change does not seem to be related to nasal disease—it is absent from the larynx; in short, it is an affection of the upper food passage.

In this type of spasmodic dysphagia the bismuth meal is arrested at the mouth of the gullet. Swallowing movements may be seen to allow only small portions at a time to escape through, the picture on the screen being interesting and instructive. With regard to the appearances seen by the endoscope I am in entire agreement with the description given by Brown Kelly. The rigidity of the tissues at the upper opening, characteristic of spasm, is a notable feature, and the thin mucosa may crack and bleed even on careful examination. In my experience such cases are entirely confined to women not by any means emotional or to be regarded as neurotic or hysterical, and the association of this dysphagia with the mucosal changes above alluded to is a subject worthy of consideration. Do the changes in the mucous membrane lead in some way to interference with the reflex movement of swallowing and so call forth spasm? It is within our knowledge that injury to the pharyngeal mucous membrane—for instance, by scalding—may sometimes be associated for a period with difficulty of swallowing. The time has come, I think, to claim for this clinical type of spasm its own, to point out its essence to the female sex without being a manifestation of an hysterical state, the possibility of its material relief by suitable treatment, and the clinical fact which I shall allude to presently, that it may be the precursor of malignant disease in the post-cricoid region. Until this is done and its position clearly defined, it will continue to be misunderstood, with regrettable consequences both to

patient and practitioner. This service I commend to the Section.

The commonest cause of dysphagia due to an organic lesion is malignant disease at the upper opening, which is almost always squamous-celled epithelioma. Here an interesting parallel may be noted with dysphagia of the spasmodic type. Both affect the superior opening very frequently in the female sex. They are comparatively rare at this site in men, in whom the incidence of malignant disease increases as we descend the oesophagus. Carcinoma is met here at a much earlier age in women; I have found it in a woman of 23. Its duration is said to be much longer, but here we are faced with the undoubted clinical fact that spasmodic dysphagia in women sometimes terminates in malignant disease. The earlier stage of this not uncommon long history in such cases is almost certainly referable to a state of spasm. I have been able on more than one occasion to determine the presence of spasm and to relieve it for a time, even some years, by the passage of a tube, and to find later the increase of dysphagia with pain and loss of flesh explained by the superposition of malignant disease in the post-ericoid region. In more than one such case the patient could assign a comparatively recent date for the alteration in her condition.

Logan Turner's statistics clearly establish that while cancer in the tongue and in the lower oesophagus is much more common in men, it shows a striking tendency in women to affect the mucosa of the oral pharynx and hypopharynx. Here again I would direct attention to the similar distribution of chronic glossitis, and raise the question whether they are related conditions. The liability of this affection in the tongue to result in epithelioma is recognized by surgeons, and there is no reason why it should not do so lower down.

In the diagnosis of carcinoma of the post-ericoid region examination by the laryngeal mirror will reveal its presence in a large proportion of cases. The upper margin of growth may be visible, or deeper-seated disease may be revealed by impaired mobility of the vocal cords. The fluorescent screen is helpful in determining the presence of such a growth and in outlining its extent downwards. Where the presence of a tumour has been ascertained we ought not to forget that the finger may be a useful means of determining its character. By means of the endoscope and suspension laryngoscopy more complete information may be gathered as to its relations and extent.

Of dysphagia produced by cicatricial contraction the result of traumatism by a foreign body or swallowing caustic fluid or from syphilitic necrosis little need be said. The etiology taken in conjunction with the local appearances seen by the endoscope will usually suffice to establish the diagnosis.

Regurgitation of food is the prominent symptom in a pressure pouch, often called oesophageal pouch, though its point of origin is always in the hypopharynx, above the upper opening of the gullet. Here the return of food is a constant sign, part of the meal being regurgitated unaltered after some hours or even days. Swallowing often produces a gurgling noise in the throat. As the pouch is nearly always on the left side fullness of the neck on that side may be noticeable and pressure over it elicit gurgling. The fluorescent screen after a bisulphite meal gives a characteristic outline of the pouch, which may be more carefully explored by the endoscope tube.

This completes a short survey of the more important affections met with at the superior opening of the gullet. The problems presented by them are of the greatest importance from the standpoint of practical medicine. I have necessarily confined my remarks to a few; others will doubtless occur to members of the Section, and I may express my confident belief that discussion of them by a body of observers possessing special training and knowledge will materially contribute to their solution.

II.—AFFECTIONS OF THE LOWER SEGMENT OF THE OESOPHAGUS.

WALTER G. HOWARTH, M.A., M.B., F.R.C.S.,
Surgeon to the Throat Department, St. Thomas's Hospital.

Of late years our knowledge of the oesophagus has in certain directions advanced enormously, and from time to time an intensive focus has been directed on certain aspects of oesophageal disease. Your Council has now thought that the time has arrived when we should make a more general

survey and crystallize our ideas with a view to arriving some consensus of opinion with regard to symptomatic and differential diagnosis of the various diseases that arise in this region. Everyone will, I think, agree that it is very important that such a step should be taken; but there can be none, I imagine, who will under-estimate the difficulty of such a task.

The organ with which we have to deal is a tube of singular complexity when its developmental history, its variety of muscular structure, and nervous control are considered, while anatomically and physiologically its exact limit, at least regards its lower end, is singularly difficult to determine. Moreover, it is placed so deeply and in such close proximity to so many important structures that a number of external considerations must inevitably be taken into account. The facts may help to explain to some extent why the normal physiology of its working is even now by no means agreed upon.

Under such conditions the investigation of pathological phenomena is apt to be fraught with many difficulties. Dr. Paterson has dealt with oesophageal disease mainly as it affects the upper part, and though it is impossible satisfactorily to divide the subject in such an arbitrary way, I propose to consider generally the lower half. The manifestations of disease in this section of the gullet are usually of the cicatricial or compression stenosis, to the various forms of malignant disease, or are a complex variety of phenomena of nervous origin. Let us consider in the first place the symptoms that we may meet with in such conditions.

In all types—I do not say in all cases—dysphagia is in the forefront of the picture; this may or may not be attended with pain, usually referred to the ericoid or to the back of the lower end of the sternum. Regurgitation of swallowed food if not actual vomiting, is usual. Irritable, useless cough may be present, whilst persistent hiccup, choking sensations, and a feeling of suffocation are often noted.

Excessive salivation is often troublesome, and this is sometimes blood-stained in character.

If the condition is at all prolonged, inanition may be a prominent feature, but marked cachexia is seldom seen.

When we come to the interpretation and relative value of these symptoms, difficulties begin to arise. Select from and group these symptoms how we will, it is impossible to present a clinical picture that is pathognomonic of any single condition. Any of them or practically all of them may be absent.

Dysphagia, usually a prominent symptom in malignant disease, may be entirely absent, as it was in one of my patients, whose only complaint was of incessant cough and occasional suffocation attacks. He had a left recurrent paralysis, and oesophagoscopy confirmed the diagnosis of malignant disease; but it remained for the post-mortem examination a few weeks later to reveal that the anterior wall of the oesophagus from the aorta to the cardia was a mass of growth. And then again dysphagia may be of only a small proportion to the size of the growth, for we know that in obstruction due to ulceration resulting from new growth there are two factors to be taken into consideration—the organic lesion itself and the spasm induced thereby. Very often the latter is responsible for nearly the whole of the symptoms.

The character of the dysphagia may be helpful, and dysphagia to solids is more usual in organic strictures and dysphagia to fluids in achalasia and allied conditions, but this is not always so. The most useful point to note about dysphagia is, I think, its variability: Dysphagia varies more often and over a wider extension in nervous phenomena than in organic disease. This is, I think, generally true, and yet we can recall cases of cicatricial stenosis in which periods of marked disability alternated with periods of comparative ease. Persistent hiccup may be a valuable early symptom in malignant disease, and I have known it precede any other by three weeks, but I have also known it as the first sign of all in achalasia.

A point of considerable clinical interest is the frequency with which the earliest symptoms of disease in the lower half of the oesophagus are referred to the upper end, so that sudden choking attacks at the beginning of a meal may be the first warning of disease in the phreno-cardiac segment. I have mentioned on a previous occasion cases of such a nature where the disease was entirely below the diaphragm.

Symptoms, however helpful they may be, are, we are told, merely disordered reflexes and so may be initiated from any portion of the tube and by a variety of stimuli, so that in our

endeavour to arrive at an exact diagnosis we must have recourse to other methods of investigation. The most helpful are x-ray examination, oesophagoscopy, and the use of the bougie under direct vision. The time has surely passed when the crude barbarity of pushing a bougie blindly into the oesophagus could be contemplated.

X-ray examination should, I think, always be conducted at the fluoroscopic screen. After the general thoracic survey has been completed in the upright position, the patient should be turned into the right half lateral position for the oesophageal examination. The value of careful and prolonged examination at the screen is very great and should always be conducted under the supervision of the surgeon himself. For this purpose, thickish bismuth emulsion is probably the best; the bismuth cachet seems to me to be not only valueless but misleading, owing to the abnormal spasm that it so often excites.

In the diagnosis between organic and functional stenosis at the lower end the shape that the bismuth takes is important. In the nervous group the shadow is very broad, regularly conical, or with a round end that bends to the left and projects somewhat below the cupola of the diaphragm; often no spot of bismuth passes into the stomach, even if examined for half an hour.

The conical form may sometimes be difficult to distinguish from malignant stenosis, but in the latter the cone is not of a regular smooth outline, but is often irregularly notched and funnel-shaped; moreover, there is usually a gradual leakage of bismuth into the stomach. A point that may be useful is the injection of atropine or papaverine. In one case in which we often watched the bismuth held up at the phreno-cardiac level for half an hour, dilating the oesophagus above it, the hypodermic injection of 4 grains of papaverine caused almost immediate relaxation, and the whole of the bismuth was in the stomach within five minutes. Atropine is apt to be disappointing, but I doubt if we use it in anything like large enough doses.

Another point that may be helpful: as the oesophagus turns forward and to the left to enter on the diaphragmatic part of its course there is a triangular space behind it. In malignant cases this space is often obliterated, whilst in spasmodic cases it is usually clear. It is, however, on oesophagoscopy that we must rely for the more exact diagnosis of many conditions, as by it alone can we determine the nature of the mucous membrane and the exact situation of any obstruction.

The characteristic white, firm, yet elastic web, often with extra fibrous strands stretching to the oesophageal wall, is typical of the cicatricial stenosis, and its level is readily ascertained, whilst compression of the oesophagus from outside, though often difficult to differentiate from intramural growths, may be conjectured from the deviation of the lumen, the shape of the slit, the mobility of the mucosa, and other appearances. In this connexion valuable help may ensue from the inflation of the oesophagus with the aid of the Moirer oesophagoscope.

The most difficult, and in some ways the most interesting, part of the investigation concerns the differentiation of the various forms of stenosis that are met with quite at the lower end of the oesophagus. Here our main task is to distinguish between organic obstructive lesions with dilatation above them, and the dilatations that result without anatomic stenosis.

It is outside my province to discuss the actual site of the obstruction in the various forms of non-anatomic stenosis, or to mention the relative importance of extrinsic or intrinsic factors; but it would be as well to suggest that achalasia, cardiospasm, hiatal oesophagismus, and other suggestive names do not connote definite diseases, but are merely manifestations of local or general disease which have led to a dysfunction of the vegetative nervous system whereby the normal reflex sequence is interrupted and the interdependent musculature of the hiatal oesophagus and the cardia put out of gear.

Even when we have diagnosed the occurrence, the interpretation thereof may be very far to seek, but this, too, may be at least helpful in turning our attention to other organs or systems for analogous phenomena and possible explanations.

These manifestations are, I think, far more common than is usually supposed and the etiology singularly obscure. This latter need not detain us now, but we should, I think, try to come to some definite conclusions as to the variety of oesophagoscopic appearances and the range of abnormality that they present.

In the long-standing well-marked case we are all familiar with the pendulous oesophagus, often sagging to the right, the mucosa thrown into folds and inflamed by the presence of the stagnant food, particles of which adhere to the walls; but when we turn our attention to the region of the hiatus the conditions that we meet with are apt to vary, and there seems to be but little agreement as to what is a typical picture.

The appearance at the hiatus, its rhythm of opening and shutting, the influence of cocaine, of acids, alkalis, and other stimuli upon it, the presence of hyperaesthetic areas and the effect of their stimulation, are all points about which we have not nearly enough systematic recorded investigations, and without which we are like sailors in an uncharted sea. At the present time these cases are coming to us for investigation at a much earlier stage, often before any great degree of dilatation has taken place, and it is, I think, from the careful investigation of these rather than from the very long standing ones that one is likely to learn the most.

Time does not permit of more than a brief mention of malignant disease, though this unfortunately provides the great bulk of the cases that we are asked to see. When fungating and projecting into the lumen of the oesophagus, the friable, freely bleeding growth presents few difficulties in diagnosis. It is the firm infiltration, sometimes localized but often diffuse, of the intramural growth that is the difficulty, and here it is that the fine bougie is particularly helpful, not only in detecting an eccentric position of the hiatus, but also in appreciating the kind of resistance that is met with, and whether or no it is possible to overcome it by gentle pressure and reach the stomach. In some cases the hiatus seems pushed up towards us as though bulged by the pressure of a firm collar, and though this condition has, I think, been described as occurring in old-standing spasmodic cases, it is, in my opinion, more commonly seen when there is a malignant growth of the subhiatal region bulging the diaphragm from below.

There is one clinical point that I should like to mention, though it is not an oesophagoscopic appearance, and that is the extraordinary frequency with which cancer of the oesophagus is associated with foul septic teeth. Looking through one's cases it is really remarkable how close is the association.

Of other conditions that are found in the lower end of the oesophagus I have of course omitted all mention of congenital atresia, of the paralytic conditions that we meet with in lesions of the central nervous system, of the various forms of oesophagitis, of syphilis and tubercle, whilst the merest suggestion of a foreign body has been suppressed. But all these conditions must naturally be taken into account in attempting to arrive at a diagnosis.

DISCUSSION.

Dr. A. BROWN KELLY (Glasgow) said:

In cardiospasm one sometimes is in doubt as to whether the closure at the lower end of the oesophagus is due to spasm or to malignant disease in the stomach. X rays and the oesophagoscope assist in the differentiation. I shall deal only with the appearances in the hiatal region observed by means of the latter.

On introducing the oesophagoscope, usually a quantity of cloudy fluid and food debris is ejected, and more or less dilatation of the lower two-thirds of the gullet is noted. On approaching what is often termed the cardia, but is really the upper part of the hiatal or diaphragmatic oesophagus, this is seen in the normal subject to be constantly opening and closing with inspiration and expiration. Even when the tube is pushed down so as to encircle the gullet this rhythmical action continues until the lumen is enlarged by the pressure so as to allow the tube to pass into the stomach.

In cardiospasm precisely the same opening and closing of the hiatal oesophagus goes on as long as the tube is kept at least 3 cm. above the hiatal oesophagus, but when it is pushed down 1 or 2 cm. farther the wall of the hiatal oesophagus gathers itself together so that the mucous membrane forms a closed rosette. This closure becomes firmer when the tube is pressed down more strongly. If moderate pressure is maintained for about a minute, the closed oesophagus usually yields and the tube glides into the stomach. In old and severe cases more pressure is needed than in early mild ones. In several instances I have been unable to get into the stomach, and in one in which this difficulty and the pain in the epigastrium led me to suspect

malignant disease, gastrostomy was done, but the stomach proved healthy. These features all point to spasm as the cause of the obstruction and do not suggest achalasia.

Various objections have been raised to the view that the affection under consideration is due to spasm. The question is asked, Why does the constant spasm not produce hypertrophy of the sphincter? Sometimes it does. But the spasm is not constant; it is intermittent, as has just been stated, and apparently it is excited by pressure for the time being above the hiatus. In the more advanced cases when the gullet always contains fluid and food the constant pressure may, of course, excite constant spasm.

But turn for a moment to the upper end of the gullet, where constant spasm may be present for ten, twenty, or more years. I have never heard that hypertrophy occurred in these cases; the investigation of the condition of the muscles involved would, however, be interesting. In passing I should like to ask the members whether they have found two varieties of spasm at the upper end, one in which the closure is effected by the gathering together of folds of mucous membrane, and another in which the greatly reduced lumen is surrounded by a sharp edge of mucous membrane, the upper surface of which is smooth so that it looks like a thin web (? contracture).

Another objection to attributing to spasm the affection known as cardiospasm is that in such cases a weighted bougie passes through the cardia easily, whereas if spasm existed there would be resistance and withdrawal would be difficult (Hurst). The resistance has been compared to that offered by the anal sphincter in a state of spasm to the introduction of the finger. Spasm of a muscle, such as the external sphincter of the anus, is not comparable with that of the cardiac sphincter, which is composed of unstriated muscle fibres. Further, there are all degrees of cardiospasm, and, as I emphasized years ago, some of these are slight and little more than a state of non-relaxation. Still, even the mild degrees of cardiospasm offer more resistance to the endoscope than does the hiatal oesophagus in the normal subject.

The contraction of the hiatal oesophagus, when pressed upon by the oesophagoscope, is apparently not due to hyperaesthesia of the mucous membrane, as I at one time believed. For the end of the pump can be passed along the hiatal oesophagus, cold water can be squirted against it, and it can be painted with cocaine without the rhythmical opening and closing being affected.

These observations and considerations seem to me to prove the following: (1) That the obstruction at the lower end of the gullet in the affection commonly termed cardiospasm is due to spasm; (2) that this spasm is predisposed to by a state of irritability of the muscle fibres, or of the nervous mechanism controlling them, in the wall of the oesophagus above the hiatus; and (3) that all the endoscopic appearances are against the theory of achalasia.

Sir STCLAIR THOMSON pointed out the improvement in methods of diagnosis possessed by the present generation. Last century disease of the gullet had to await attention until it had produced a stricture. The latter could only be investigated by the blind use of a bougie. Now, with the x-ray examination and direct endoscopy matters were very different. He quoted two cases to show that the progress of malignant disease may be very slow and that spontaneous improvement and increase of weight may occur even in a case of epithelioma. He made an appeal for the routine examination of the oesophagus in all affections of the chest and abdomen, pointing out that he had made an analogous appeal in regard to the accessory sinuses of the nose many years ago. He also deplored that students had not the opportunity in this country, which they had in America, of acquiring the art of endoscopy by practising on live but anaesthetized dogs.

Mr. W. S. SYME (Glasgow) said that he certainly thought there was a definite condition of spasm of the lower part of the oesophagus. Moreover, this was not such a rare condition as was supposed, and in consequence he could not subscribe to the opinion that such a large proportion of cases of oesophageal obstruction as 90 or 95 per cent. were due to malignant disease. The spasm of the oesophagus was not always at the opening through the diaphragm. In one case, which he was able to demonstrate the spasm occurred about an inch above that opening; it could not therefore be due to spasm of the crus of the diaphragm. In dealing with spasm of the upper opening of the oesophagus he did not think it mattered for practical purposes whether this arose first at the lower part of the pharynx or

the upper part of the oesophagus. It would overflow from one to the other. The spasm might be set up by various conditions, and might vary in severity. In one case it was so severe that almost complete starvation was caused. It was cured by the amputation of an elongated uvula. Many cases of spasm of the upper part of the oesophagus were due to irritation by post-nasal discharge due to nasal accessory sinus disease or other cause. To return to what was called cardiospasm he thought it should be stated that there was not by any means always dilatation of the oesophagus above. Dr. Kelly inquired as to the presence of a web at the upper end of the oesophagus. He had seen such a case. The condition in which folds of the mucous membrane were found at this part was not uncommon. On passing the oesophagoscope the impression was obtained that this was the oedematous mucosa above malignant disease, which as the oesophagoscope passed onward was found to be absent.

The PRESIDENT said that he agreed with Dr. Syme and other speakers in saying that the selection of the subject of discussion had proved very fortunate. Some doubt had been thrown upon this, but the result of the papers read by Dr. Paterson and Mr. Howarth, with the remarks which had followed subsequently from the different speakers, showed that the subject was of great interest, that there was much to learn, and he ventured to think that the result of the discussion would be a great stimulus to further investigation of many points we did not fully understand because of the apparently simple action or function, the explanation of which was taken for granted.

For example, he thought that the question of reflex action causing great spasm of the oesophagus and often difficulties in diagnosing, as well as cardiac spasm, should be very carefully reinvestigated. One thing, the President said, was quite certain—that a search would have to be made farther afield for causes of spasm.

He mentioned the case of a patient who suffered from severe chronic obstruction in the oesophagus, who had been to a number of the hospitals in London, and the specialists in each hospital, many of them distinguished men, diagnosed organic stricture of the oesophagus. He fell latterly into the hands of Mr. Mayo Collier, who brought the case before the British Rhinological, Laryngological and Otological Association. The man came to his wards dying; a post-mortem examination was made, and the parts showed that the necrosis was not in the oesophagus at all, but at the cardiac end of the stomach. So here there were errors in diagnosis by a number of skilled experts, but it shed light upon severe spasmodic stricture of the oesophagus. Of course, the methods of examination were crude as compared with the direct examination by means of the oesophagoscope of to-day and the x-rays.

The President said that in certain cases of this kind we had to go farther afield, and he mentioned the case of a young man who was greatly troubled with obstruction of the oesophagus and cardiac spasm, and where the x-rays by means of the screen had thrown great light upon the case. The patient was in a darkened room on a table, with the tube below; the bismuth meal was administered and passed fairly easily into the stomach. Almost immediately the stomach assumed a vertical position, and it became pear-shaped, with a large dome pressing against the diaphragm. After a few minutes the heart began to flutter and violent movements were easily seen on the screen, and it was important to note that this disturbance of the heart action was seen before the patient said, "That is the fluttering of my heart coming on again."

The President said that before proceeding farther he would like to point out what the normal function was and what took place after food entered the stomach. The cardiac end of the stomach was closed by the action of the sphincter in the region of the lower part of the oesophagus and stomach. At the same time the pyloric end of the stomach was closed, and afterwards the movement of the viscus for digestion proceeded. After a time the stomach contracted and food was passed into the duodenum, going over in a mass. This action at both ends of the stomach took place again during the movements for digestion, and at the proper time the food again passed downwards into the bowel. It was a function of the oesophagus to prevent the food coming back into the mouth. In other words, the action of closing the cardiac end of the stomach and oesophagus was necessary to the passage of the food in the right direction, or regurgitation would take place.

They were apt to consider that the function of the oesophagus consisted in a simple opening of the tube to let the food into the stomach, a period of rest following, but that was not the case. The oesophagus in conjunction with the pyloric end of the stomach was constantly in action to keep up the proper tension and direct the food onwards.

The President assured Dr. Paterson and Mr. Howarth that the members of the Section of Laryngology had genuinely and thoroughly appreciated all their work and were very grateful to them.

PLASTIC OPERATIONS FOR NASAL DEFORMITY.

Dr. DOUGLAS GUTHRIE showed a series of photographs illustrating the results of plastic operations in fourteen cases of nasal deformity. In three cases the disfigurement was the result of syphilis, in two cases lupus was the cause, and the remaining nine cases were of traumatic origin. The photographs demonstrated the superiority of costal cartilage transplantation over the injection of paraffin, in the treatment of saddle or sunken nose. The majority of the cases had stood the test of time, the cartilage remaining unaltered in its new position.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SOLUTION OF TRINITRIN IN ACUTE NEPHRITIS.

I DESIRE to call attention to the great value of liquor trinitrini in the treatment of acute tubular nephritis, accompanied with dropsy. It is said that there is nothing new under the sun, but I struck upon this remedy by pondering over the question: What prevents a speedy cure of our cases of acute nephritis? I have watched my cases for the last twenty-five years in Glasgow; and, in my experience, to remove the last trace of albumin from the urine of these patients is by no means easy. I think I can safely say that it is quite a common experience to treat the patients with iron tonics and diuretics for six to twelve months before we accomplish our purpose.

The last four cases cleared up so quickly—from a few weeks to a few months—that I venture to state how this was achieved. Three of the patients were up in years, but one was about 30. The urine contained a good deal of albumin. Two of the cases had orthopnoea, due to oedema of the bases of the lungs. One—an old hemiplegic—passed a good deal of blood. His pulse-tension was so high that I predicted that he might have a fit, and he had a seizure that night. All the patients made a speedy recovery. Iron tonics were given as soon as the albumin left the urine. The diet was light, limited to fluids, either milk or soups. Purgatives were not employed. The following mixture was given:

R Pot. acetat. ... 3v
Liq. trinitrini ... mxxxij
Tr. card. co. ... 5iv
Aq. ... 3vij

Half an ounce of this mixture, in water, was given every three hours until the symptoms abated, then thrice daily.

Glasgow. JOHN T. MACLACHLAN, M.D.

RUPTURE OF QUADRICEPS TREATED BY SUTURE.

The following somewhat rare accident, and the treatment adopted, may be of interest. On June 6th Mrs. E., aged 62 years, slipped on going down some steps, and after making a violent effort to recover her balance fell down.

In bed at home, shortly afterwards, she stated that she could not lift her right leg, in which she suffered considerable pain. There was some swelling at and above the right knee-joint, and there appeared to be a gap in her quadriceps extensor muscle about an inch above the patella. She was unable to put this muscle in action. An x-ray screen showed no fracture of the patella. I decided to explore the tear in the quadriceps extensor, and under ether a large flap of skin was raised above the patella, and a complete division of the muscle was discovered, but, curiously, no blood clot or bleeding was found at the point of division. Mattress sutures of thirty-day catgut were used, and the wound healed by first intention. She has now complete use of her leg, can lift her heel off the bed with the knee extended, and the gap felt above the knee after the accident has entirely disappeared.

The only similar case I have ever seen during thirty years of practice was that of an old gentleman over 70 years of age;

in his case no operation was performed, a back splint and strapping being applied; the muscle never united, and a gap remained permanently.

Kettering. LESLIE W. DRYLAND, L.R.C.P., M.R.C.S., D.P.H.

ABNORMAL ANTERIOR FONTANELLE.

ON making a vaginal examination in a case of labour lately I felt anteriorly what I took to be the posterior fontanelle. There was a depression and three sutures and nothing more. There was no caput succedaneum. Later, as I put on forceps, I was surprised to find the posterior fontanelle lying posteriorly. That this was so was proved by the long rotation of the head as I delivered very easily. After birth I discovered the reason of my mistake. The anterior fontanelle was represented by a dimple where the four sutures met. It was not as usually found and described: for example, in Shears's *Obstetrics* the anterior fontanelle is said to be distinguished in that it is large and soft, and in Berry Hart's *Guide to Midwifery* the anterior fontanelle "is known by its shape and size." There were of course four sutures, but the possibility of such a fontanelle was not known to me, so I had not searched for the fourth suture. There was no head moulding.

THE TREATMENT OF PULMONARY TUBERCULOSIS BY TUBERCULIN.

OPINIONS as to the value of tuberculin in lung tuberculosis are so conflicting that the following figures may be of interest. They refer to the present condition of patients treated during the years 1910 to 1915. Only patients who had tubercle bacilli in the sputum are included; no "doubtful" cases are considered. They came under my care while holding the post of medical officer to the Oxfordshire Association for the Prevention of Tuberculosis, and were domiciled not only in the city of Oxford, but also in the surrounding country districts. Owing to the distances from the central dispensary at which the patients lived only a certain number could attend for treatment by tuberculin. Thus, with the exception of a few cases in which the patient's own doctor undertook the administration of tuberculin, it was possible, by virtue of geographical considerations, to have the advantage of a control series. The following table shows the results of treatment of 429 cases of pulmonary tuberculosis; of these, 346 were treated without tuberculin, and 83 with tuberculin.

	Treated without Tuberculin.		Treated with Tuberculin.	
	No.	Per Cent.	No.	Per Cent.
Dead ...	311	89.9	33	45.8
Alive ...	18	5.2	41	49.4
Lost sight of ...	17	4.9	4	4.8
Totals ...	346	100.0	83	100.0

From the table it will be seen that of the 83 patients treated with tuberculin there are 41 (49.4 per cent.) now alive, as against 5.2 per cent. of the 346 patients who received "general medical treatment." Included among the 38 cases who were treated with tuberculin and who are now dead are 3 patients who died from causes other than tuberculosis—one from *post-partum* hæmorrhage, and two during the influenza epidemic, having enjoyed up to their death a very reasonable amount of health. One of the 311 cases was killed in the war.

The enormous mortality among the "open" cases of tuberculosis of the lungs in the dispensary class of patient, after a period of years, will be observed, notwithstanding the advantages these patients had of living in the country. The method of tuberculin administration employed was on the lines of that recommended by Cnamac Wilkinson—namely, gradually increasing doses, twice weekly, of bovine tuberculin (P.T.O. and P.T.), commencing with 0.0005 c.c.m. of P.T.O., and continuing up to 1 c.c.m. of P.T., with, in some cases, a few injections, at the end, of Koch's old tuberculin (T.A.) until 1 c.c.m. was given. The course of treatment consisted of about forty injections, lasting roughly six months, at a cost of less than a week's stay in an institution.

Rebichus.

INJURIES OF THE PERIPHERAL SPINAL NERVES.

DURING the last few years numerous monographs have appeared dealing with the treatment of injuries of the peripheral nerves, and; although by this time most of the problems which confronted us in the early months of the war have been solved, each new publication appears to add some information to our knowledge of this fascinating subject. In the *Treatment of Injuries of the Peripheral Spinal Nerves*, by Sir HAROLD STILES and Dr. FORRESTER-BROWN,¹ we have the most complete and detailed account of the operative treatment, and almost two-thirds of the book is devoted to this aspect of the subject.

Part I contains a very concise and accurate account of the anatomy of the spinal nerves, and attention is carefully directed to most points of greatest significance for accurate diagnosis. The indications for operation and the choice of the type of operation are clearly set out, and these, together with the section on the factors which influence prognosis, are in agreement with the conclusions arrived at by most workers in this field. In their discussion on recovery the authors state that they have found Tinel's sign valuable, although its absence was no proof that recovery was not occurring. It is doubtful whether this statement will meet with general approval, since some workers have found Tinel's sign of very limited service and regard it as not infrequently misleading. The table showing the recovery after suture in sixty-nine patients would be more valuable had information been included as to the interval which had elapsed between the reception of the injury and the time of the suture, and had it been possible to follow the recovery after operation for fully two years in more than fourteen of the cases.

Part II is devoted to a most complete account of the operative treatment. The best exposure for each nerve at different levels, the surgical anatomy, and the fullest details of the methods which have furnished the best results are all admirably presented. This part represents a very valuable contribution to knowledge, and includes much original matter which is based upon a very extensive experience of the surgical treatment of peripheral nerve injuries.

Part III deals with the operation of tendon transplantation, and here again the fullest details are included and attention directed to all factors which may influence the functional result. To compensate for the loss of the intrinsic muscles of the hand an ingenious operation is described by which the insertion of one of the flexor tendons is sutured to the extensor communis tendon, just distal to the knuckle, so as to make it a flexor at the metacarpophalangeal and also an extensor of the interphalangeal joints.

The volume contains a good index, and is well and freely illustrated by diagrams, photographs, and coloured plates. We have read this monograph with much interest and pleasure. We commend it to surgeons, who, we believe, will be unanimous in agreeing that it is a very agreeable contribution to surgery.

CLINICAL STUDIES FROM LEYSIN.

THE new volume of the series published under the title *Études sur la Tuberculose*² consists of a collection of thirty-one papers by no fewer than eight workers at the well-known Swiss station of Leysin. Since the publication of the last volume six years have elapsed, during which the war made severe roads on the time and occupation of those on the staff of the public sanatoriums, and it is a matter for congratulation that during such a period they have found it possible to accomplish so much original work; a considerable part of it as involved the careful observation of cases over stretches of several months. The book is divided into three sections. The first, dealing with clinical studies, is opened by Dr. Jaquerod, who considers the relation between erythema nodosum and tuberculosis. While holding that the skin lesion is of a tuberculous nature, he regards it as due to no more than a temporary haeciliaemia occurring in a patient suffering from a latent focus. So far from being

of grave prognostic significance, there would appear to be no more danger of the supervention of active tuberculosis than in the case of patients who have never suffered from the disease. In a later section Dr. Burnand explains the classical antagonism between mitral stenosis and the development of tuberculosis by showing that it is apparent rather than real. In fact, the opposite is the case; the two are frequently associated. The valvular lesion itself is, he holds, of tuberculous origin occurring in a subject having a small focus in the lung, which pursues a slow, benign, non-destructive course, and hence is generally overlooked in the clinical examination. However suggestive his clinical studies on this question may be, he would carry more conviction if he could bring to his aid the confirmation of pathological observations. The effect of the influenza epidemic of 1918 on the patients undergoing treatment is shown to have been comparatively slight, and there is little evidence to indicate that it was responsible for the activation of more than a small proportion of cases which developed tuberculosis in the subsequent few months.

The second part of the book is of particular interest, dealing, as it does, chiefly with the question of artificial pneumothorax. For the greater part of the work on this subject Dr. Burnand, the medical director of the sanatorium, is responsible. Regarding it mainly from the point of view of its curative effect, he brings forward his own statistics relating to 133 patients treated by this method during the course of the last nine years. The discrepancy existing between the immediate and the after results is striking. However excellent may be the effect on the lung during the two or three years of compression, the ultimate prognosis for the patient is by no means too bright. Only too common is it for those in whom the disease has been arrested for three, four, or five years to succumb eventually to tuberculosis. Not the least point of interest is the obvious disagreement noticeable between the views of Dr. Burnand and those of Dr. Jaquerod on the subject. The latter still regards the operation as of only occasional value, and is very emphatic in stating that a cure obtained by hygieno-dietetic measures alone, without the assistance of artificial therapy, stands a far greater chance of remaining permanent than one obtained by the help of now-faught methods, however skillfully applied. He, however, recognizes the value of tuberculin, and, indeed, deals with it in a very luminous manner, the indications for its use being definite and precise.

Finally, in the last section various studies are presented, such as those dealing with blood pressure, Wildbolz's ro-intradermal reaction, and certain prophylactic aspects of the disease. To all these whose interests lie principally in clinical medicine this book will make a strong appeal.

THE AMERICAN GYNECOLOGICAL SOCIETY.

THE forty-fifth and forty-sixth volumes of the *Transactions of the American Gynecological Society*³ contain much that is of great interest. The meetings of the society are reported more or less verbatim, and where space is not a matter of consideration this method adds a piquancy to the reading which is lacking in condensed reports. Moreover, they show that this society is no mere mutual admiration society, some of the criticisms being distinctly trenchant. One of the most interesting items in the volume is a report presented by Dr. G. W. Kosmak of a committee appointed to consider how best the society could advance gynaecology and obstetrics. It is full of suggestions which are of general applicability and will assuredly prove fruitful. The discussions reported cover a wide range of subjects, mostly obstetrical. Obstetric anaesthesia is discussed by Dr. E. P. Davis with particular reference to the more modern nitrous oxide-oxygen and ether-oxygen methods. Induction of labour is discussed by Dr. C. B. Reed, who advocates the use of Vorhees's bag, and Dr. B. P. Watson, who recommends repeated doses of pituitary extract 0.5 c.cm. at intervals of twenty to thirty minutes. The congress apparently felt apprehensive at the thought of employing such large doses of so potent a drug, but Dr. Watson said that he had had no bad results and a high percentage of success. Professor De Lee described his conduct of a confinement *de luxe* by the prophylactic use of forceps and episiotomy, followed by rapid expression of the placenta. This procedure was vigorously and almost unanimously condemned. Professor Whitridge

² *Études sur la Tuberculose (5-ième Série)*. Station Climatérique de Leysin. Par les Docteurs Burnand, Grosjean, Jaquerod, Pignat, Reynier, Rossol, Sillis, et M. J.-V. Bergen, Docteur en Sciences. Paris: Masson et Cie. 1922. (Demy 8vo, pp. 518; illustrated. Fr. 15 net.)

³ *Transactions of the American Gynecological Society*. Edited by G. G. Ward, Jr., M.D. Vols. 45 (1920) and 46 (1921). Philadelphia: W. J. Dornan. (Med. 8vo, pp. lxxiv + 482; illustrated.)

Williams contributed a valuable paper on the Wassermann reaction in obstetrics, in which he emphasized the value of active antisyphilitic treatment during pregnancy. Extraperitoneal Caesarean section, the operative treatment of sterility, artificial insemination, acidosis in operative surgery, the stages in the transition from benign to malignant conditions in the ovary, uterus and vulva (by Dr. T. W. Eden), the microscopic anatomy of the pregnant tube, the value of a "follow-up" system for obstetric hospitals, haemorrhage into the pelvis not due to tubal pregnancy, idiolum and cancer, leucin cysts and hydatidiform mole, the status of the intrauterine foetus, pregnancy and labour associated with cardiac disease, the teaching of obstetrics in a modern medical school, basal metabolism in pregnancy and the puerperium, pneumoperitonem and roentgenology as aids to more accurate obstetric and gynaecological diagnosis (by Dr. Renben Peterson), endocervicitis and eversion treated by the nasal cautery tip (Dr. R. L. Dickinson)—these are only some of the papers included in these volumes, but the enumeration will serve to show the catholicity of the society's interests. Gynaecologists on this side of the Atlantic will find much of interest in these volumes and not a little of real importance. The society is to be congratulated on its vitality and on the financial strength which, in these days of high prices, permits the publication of such handsome volumes.

PASTEUR AND HIS WORK.

M. L. Descur in his book *Pasteur and his Work*⁴ gives an account of Pasteur's researches extending from his early studies on crystallography to his crowning triumph in the production of immunity. His epoch-making contributions to the advance of science are, to quote the words of Dr. Émile Roux, "described with a precision, an orderliness, and an emotion worthy of so great a subject." The book deals almost entirely with Pasteur's work, but it contains many quotations from his writings and those of his critics, so that a living interest is imparted; especially is this true of the chapters on fermentation and spontaneous generation. Other books on Pasteur give a better insight into his character and habits, of which in this volume we only gain occasional glimpses, but none do better justice to his prodigious labours and the amazing success of his researches.

Pasteur was born nearly a hundred years ago (December 17th, 1822), and the centenary is to be celebrated next spring. He showed no particular promise in his youth, and in 1842 he became "bachelier ès sciences" with the least possible distinction, the future chemist receiving for his medical paper the comment "médiocre." Nevertheless, the thoroughness, originality, and conclusive results of his early researches on crystals made a great impression on the minds of his teachers. From the study of crystallography he turned to fermentation, and from this to the then much debated question of spontaneous generation. He always had in view the practical outcome of his laboratory labours, and M. Descur has clearly indicated how Pasteur's discovery of bacteria as the cause of fermentation led him on step by step first to the diseases of silkworms, and next to the study of the contagious diseases of man.

The medical profession was, on the whole, slow to appreciate the value of his work on bacteria as the cause of disease, but Pasteur knew how to defend his point of view and could retaliate with vigour when attacks were made on him. When engaged in the study of puerperal infections he was sitting one day in the lecture theatre of the Paris Maternity Hospital listening to a discourse from one of the physicians on the causes of epidemics in maternity hospitals: "What causes epidemics is nothing of the sort: it is the doctor and his assistants who carry microbes from a sick woman to a healthy one," he cried. Later in life he had received recognition and homage from all branches of the medical profession, and at his jubilee in 1892 Lister expressed the admiration of all the world when, addressing Pasteur in public, he said, "Truly there does not exist in the whole world an individual to whom medical science owes more than to you."

We recommend M. Descur's book in its English dress to the general reader, to medical practitioners, and to those bacteriologists who, coming to the study of the science after its foundations had been well and truly laid, are perhaps not sufficiently acquainted with the labours of their predecessors.

⁴ *Pasteur and his Work*. By L. Descur. By A. F. and B. H. Wedd, M.D. Seeo Dawin, Ltd. 1922. (Mod. 8vo. pp. 256: 1

GOLF.

About three weeks ago at the end of one of the many atrocious rounds of golf for which I have been responsible I came to the conclusion that my case was incurable. On the advice of *Punch*, and believing "Ex America semper aliquid novi," I studied *What is the Matter with Your Golf Game?* by Joseph Collins, M.D., neurologist. No benefit resulted. The Editor of the *BRITISH MEDICAL JOURNAL* suggested that I should try the Wetherens' book.⁵

It was an unusual idea that two people of opposite sexes should combine to write a treatise on golf. Mr. H. N. Wethered, who writes a short prefatory note, tells us that the original idea was that his daughter Joyce should write some sort of treatise on golf for young players. To avoid narrowing the field his son Roger contributed the technical sides of iron and wooden club play, and chapters on Oxford and American golf. In some respects this subdivision has not improved the volume; there is a tendency to repetition, and the error is almost unavoidable in a co-operative arrangement of this description.

In an interesting and entertaining chapter on "Ladies' golf" Miss Wethered raises the question of the difficulty which women have in the art of overhead throwing. She believes that this manœuvre is closely related to the action of iron club play, with which, according to Miss Wethered, women have considerable difficulty. It is of interest to medical men to notice that Miss Wethered suggests that the difficulty may arise from the "absence" of some necessary muscles. Possibly this is the story of Adam's rib in another form, but Miss Wethered may be comforted to know that her sex is under no handicap in this connexion; "want of development" would be a more correct description.

While the volume is in many ways very charming, it is not a book which can be confidently recommended to beginners. Neither of the authors possesses the art of making description easy to follow, and the male member of the combine may even be accused of unnecessarily complicating what will always remain sufficiently difficult.

It is unusual for our instructors in the art of golf to recommend a wooden club because of the size and shape of its striking face. Roger Wethered advises for the beginner a club which he describes somewhat as follows: "A fine breadth of face which is shaped in the form of a bulge designed to counteract a tendency to slice or pull. The hitting surface is deep enough to satisfy the fooler, who is inclined with the ordinary club to strike the ball below its centre." The wisdom of inserting advice of this description is doubtful. No one appreciates better than Mr. Wethered that the rhythm and the movement of a wooden club stroke are too complicated to be materially affected by minor structural details of the club head.

The book will arouse the old controversy as to the parts which the wrists play in the beginning of the driver swing. Both authors are opposed to an early movement of the wrist; this is contrary to the teaching of many first-class professionals, and it is interesting to notice that the photographs which demonstrate Miss Wethered's drive would appear to indicate early turning of the wrists. The advice to late beginners to cultivate a short back swing is good. A great deal of bad language would be avoided if this precept were more often followed.

The reader will be disappointed to observe that in the chapter which deals with American golf, and alludes more especially to the American invasion at Hoylake, no mention is made of Mr. Hunter, the amateur champion of last year. No amateur has done more for the fighting spirit of British golf. Surely it is savouring of exaggeration to draw such a strong distinction between the styles of the British and American amateurs as is done by Mr. Wethered. He leaves one with the impression that he ascribes the excellence of American golf to certain peculiarities of the American technique, but it is to be hoped that his deductions in this respect are incorrect.

The book is written for amateurs, and therefore it makes much of the faults of the game. A greater clearness of description, combined with simplicity of language, would have increased the value of the book; it is, nevertheless, an interesting contribution to the literature of the game, as representing the views of two leading British amateurs.

⁵ *Golf from Two Sides*. By Roger and Joyce Wethered. London: Longmans, Green and Co. 1922. (Demy 8vo. pp. 197; illustrated 10s. 6d. net.)

NOTES ON BOOKS.

A System of Clinical Medicine,^a compiled by the late Dr. T. D. SAVILL, maintains its popularity under the editorship of his widow, Dr. Agnes Savill; the sixth edition has just appeared. The special feature of this work is that the diseases are dealt with primarily from the point of view of the symptoms they present, the symptoms being afterwards traced to their causes. With the assistance of experts in various subjects the new edition has undergone a thorough revision, and a number of additions have been made. The chapter on diseases of the lungs has been revised by Dr. James Torrens, and those on immunity and clinical bacteriology by Dr. Skene Keith. Dr. Harry Campbell, who for a previous edition had rewritten the section on nervous diseases, has again brought it up to date. As has been said, the book in its construction has a character which will continue to appeal to many readers.

In the small book entitled *the Students' Guide to Vaccination* Dr. ARCHIBUSON ROBERTSON gives a clear and concise account of the whole process of vaccination. He gives advice as to the examination of the child, the instrument to be used, the preparation of the skin, the progress of the pox, and the abnormalities which may in rare instances occur. He briefly discusses also human and calf lymph and the glycerination of lymph, the duration of vaccinal protection, the need for revaccination, and the law in England, Scotland, and Ireland. But the little work is more than a mere guide to the practice of vaccination. About one-half of it is devoted to the subject of small-pox; its symptoms, varieties, diagnosis, prevalence, mortality, and prevention. The brief historical notes on the prevalence and fatality of small-pox in pre-vaccination times, the practice of inoculation introduced through the influence of Lady Mary Wortley Montagu, the discovery of vaccination by Jenner, and its marvelous effects on prevalence and mortality, ought to stimulate some of the readers of the book; after they have graduated, to follow up the subject as a special study in epidemiology and preventive medicine.

It might be expected that a notebook for students and a ready work of reference for the busy practitioner—this is Mr. T. W. WIDDOWSON's description of his *Notes on Dental Anatomy and Dental Histology*—would contain a valuable array of facts helpful in daily practice. But this is not the case; the subjects dealt with are essentially examination subjects, and, as far as the student is concerned, he will find a large range of extremely interesting, but oftentimes very academic, subjects, briefly but thoughtfully noted. The varieties of tooth, enamel, and dentine found in birds, beasts, and fishes; the theories concerning the evolution of the cusps of the human molar; the structure of whalebone: these and a hundred similar subjects form the great bulk of the book, and one is left wondering, not why Mr. Widdowson has set them forth in compressed form, but what purpose they serve in an overcrowded curriculum. While the general execution of the work is good, there are a few errors and ambiguities which should be removed. What value has such a statement as, (enamel) "being an epithelial structure the same poison which is produced by the germ of scarlet fever, etc., causes the death of epithelial cells, of the skin, of the hair bulb, of the mucous membrane, and of the enamel organ," as an explanation of hypoplasia of enamel? What interglobular spaces are referred to on page 15? Is it a fact that syphilis, struma, and exanthemata accelerate eruption of the teeth? On page 34, under the heading "lamellae," we read, "they are more numerous in young than in completed cementum. As age advances the lamellae increase in number and the cementum in thickness"—apparently contradictory statements. Is the author perhaps thinking of pathological increase in later life? Why, on page 43, is a description of the glands draining the tooth-bearing areas thrust into a note on the question of the existence of lymphatic vessels in the tooth-pulp? We may ask, too, why such words as "Zahnleiste," "Lippenfurche," "anlage," need be used? The illustrations are clear and appropriate, but we wonder why, in the diagram showing the state of calcification of the teeth at various ages, the enamel is depicted as calcifying first at the tip of the finished tooth and not at the tip of the dentine papilla. At the "cram" stage students will find the book useful.

^b *The Students' Guide to Vaccination.* By W. G. Aitchison Robertson, I.D., D.Sc., F.R.C.P.E. London: A. and C. Black, Ltd. 1922. (Cr. 8vo. 16 pp. 3s. 6d. net.)

^c *Notes on Dental Anatomy and Dental Histology (Human and Comparative).* By T. W. Widdowson, L.D.S. Fourth edition. London: John Bale, Sons, and Danielsson, Ltd. 1922. (Fcap. 4to, pp. viii+233; 86 figures. 15s. net.)

*From Switzerland to the Mediterranean on Foot*⁹ is the story of a tramp of an unusual kind, for it can have occurred to few people to walk from the Rhone Valley to the Riviera, and to fewer still to choose midwinter for the expedition. Dr. J. B. WINTER and his wife started from Sierre on December 3rd, 1919, and reached Cannes on February 5th, 1920; of the sixty-five days thirty-six were actually spent in walking. The total distance was 488 miles, and the average for each walking day was 13½ miles, so that it was not a hurried journey, and the travellers were afforded an opportunity of admiring the scenery, which in winter is, we can well believe, more imposing than in the summer. The travellers experienced no serious hardships, though many discomforts, and Mrs. Winter on one snow-covered pass suffered from frost-bite; on a few occasions they ran some risk. It is not everyone who would care to trust to telegraph poles as a guide down an unknown valley through fresh snow, and at one point a risk was taken on a frozen slope which was, perhaps, not justifiable. The route was down the Rhone Valley and along the southern shore of the Lake of Geneva to Thonon, then south to Annecy and Grenoble, thence south-west to Briançon, and then more or less south to Venoc, Grasse, and Cannes. Dr. Winter has told an interesting story in a simple direct way. He has appended some notes on a few mountaineering expeditions in Switzerland.

The American Pediatric Society has published its thirty-third volume of *Transactions*, containing a report of the proceedings of its annual meeting held last year. It is edited by Dr. JOSEPH BRENNEMANN. The paper it contains, numbering forty-two, deal with a wide range of subjects; as is proper, many are concerned with the feeding of infants and children. A paper by Blackfan-Little of Cincinnati on the thymus in infants seems worthy of special mention; it is founded upon clinical and radiographic studies; it would appear that the application of x-rays is of advantage when symptoms are believed to be due to persistent or enlarged thymus.

MEDICINAL AND DIETETIC PREPARATIONS.

Chenopodium Oil.

CHENOPODIUM OIL has been adopted by the International Board of Health as a remedy for hookworm, and is recognized as having specific value in treatment for round worms; different varieties of the oil have been found to possess varying degrees of toxicity. Since the active constituent ascaridole is highly susceptible to decomposition there are good grounds for presuming that the toxic constituents consist of products of decomposition formed during distillation. We have received from Messrs. Burroughs Wellcome and Co. a specimen of chenopodium oil in gelatin capsules. They have been examined analytically with results showing that the oil contains not less than 90 per cent. of unaltered ascaridole. This high percentage is a trustworthy indication that the oil has suffered no appreciable decomposition in the preparation, and further that a concentration of the active constituent has been effected, for the average proportion of ascaridole in chenopodium oil is about 60 per cent. It is not certain whether ascaridole may not itself be toxic, particularly to idiosyncratic patients, but whatever the toxic effects of the substance itself as distinct from those of associated constituents, it will be a satisfaction to have an article in which the latter are greatly reduced in amount, which has a constant composition, is rich in the important therapeutic agent, and is appreciably free from products of decomposition.

MEDICAL AND SURGICAL APPLIANCES.

Fine Adjustment Valve for Oxygen.

Dr. K. B. PINSON, Anaesthetist, Manchester Royal Infirmary, has designed the valve here illustrated to replace those at present in use. The action, which is quite different from existing makes, is, he states, easy and fine, and the closure absolute. The spindle is rustproof, the milled head is marked by divisions, and the nose contains a filter to prevent the entry of gritty particles from the cylinder itself. Dr. Pinson believes that the use of this valve will prevent much waste of oxygen and give a very delicate control where such is needed. The valve is made in several different types to fit all makes of cylinders. Cylinder valves of similar internal construction, for use with a foot key, are also made, the control of which, while quite satisfactory, is not so nice. The price of the former is 15s. and 16s. 6d., according to type; and of the latter 20s. The makers are the Condensed Gas Co., Ltd., 59-63, Grosvenor Street, All Saints, Manchester.

THE HEALTH AND HEALTH ADMINISTRATION OF ENGLAND.

(Continued from page 488.)

THE INSURANCE MEDICAL SERVICE.

CONTINUING our notice of Sir George Newman's report on the state of the public health (1921) we may take next the sections dealing with the insurance medical service. He is of opinion that the principal necessity is "a period of composure free from frequent modification and administrative change." Some changes, however, are inevitable; and some development in certain directions is generally desired. He observes that the insurance practitioner treats the patient, furnishes returns, demonstrates loss of time and work due to sickness, and contributes to knowledge of the causes of morbidity. It is desired also that he should co-operate with the medical officer of health, and advise and educate his patients in the manner of healthy living. In all these respects substantial service is being rendered.

Of the total 13,485,000 insured persons in England and Wales in 1921 there were on doctors' lists 12,506,000 and on approved institution lists 159,700, whilst 42,500 made their own arrangements for medical treatment. The insurance doctors numbered 12,079. In every area there is a fixed maximum, which can never exceed 3,000, and is often 2,000 to 2,500. About 34 per cent. of doctors have less than 600 on their lists, about 30 per cent. between 600 and 1,200, and only 14 per cent. (many of them with partners or assistants) have over 2,000. The chemists giving service are numbered 9,105, and the prescriptions dispensed about 29,550,000; the estimated cost of drugs £1,283,000.

Medical Records.

The keeping of records was resumed at the beginning of 1921, new forms being adopted. They are necessary in relation to an expenditure of £8,000,000 a year, and are said to be of value in the future interest of the patient. Collectively they may have statistical value in regard to disease incidence. About 9,000 visits were paid to doctors by the Ministry's medical staff for inspection of records, and it is recognized that an honest endeavour is being made to keep them properly. They are proving of great value.

Regional Medical Staff.

There are thirty-two regional and five divisional officers, who act as referees regarding incapacity for work, and discharge other duties. More than a year's experience of their work is said to prove that their appointment was amply justified; they have gained the general confidence of all concerned.

Certification of Incapacity for Work.

The statistics of referees' experience as to incapacity for work must be of particular interest to insurance practitioners. The total number remitted to the regional medical officers in 1921 was 69,543, of whom 1,543 were referred by practitioners, 153 by Insurance Committees, and the rest, amounting to 97.6 per cent. of the whole, by approved societies. The reason presumably was that they were doubtful of the medical attendant's certificate that the member was unfit for work. The results are striking. Including cases carried over from 1920, and omitting cases not completed at the end of 1921, we find from Sir George Newman's figures that 68,277 cases are in question. Of these 26,935 were found incapable of work, and 14,562 were not incapable; 26,780 "either voluntarily declared off the funds or for some other reason failed to present themselves for examination." Reducing the figures to rates, it thus appears that of 1,000 referred insured persons who had been receiving certificates of incapacity for work, and presumably obtaining sickness or disablement benefit from the funds of approved societies, only 392 were really found incapable, whilst 213 were found not incapable, and 395 went back to work of their own accord, or at least did not venture to submit themselves to the ordeal of the medical referee.

Disciplinary Cases.

Reports submitted to the Ministry by Medical Service Subcommittees in accordance with the Terms of Service numbered 339; of these 129 related to alleged failure to give adequate treatment, 83 to complaints of improperly charging fees, and 92 to medical certificates. In 48 cases deduction was made from Exchequer grants, and took effect against the practitioner's remuneration. Against decisions of Insurance Committees there were 16 appeals, 11 of them by doctors and

5 by insured persons or societies; 6 of the 11 were allowed, 4 dismissed, and 1 withdrawn. In 10 cases doctors appealed against the withholding by Insurance Committees of part of their remuneration on the ground of extravagant prescribing; 2 appeals were dismissed, 1 was allowed, in 3 the amounts withheld were reduced, 1 appeal was withdrawn, and 3 were still undecided. Elovon representations were made to the Minister for removal of names from the medical list: three were based on convictions in courts, and the rest related to allegations of neglect of patients or failure to give proper service; two names were removed from the list, one was allowed to resign on condition of not reapplying without consent, one was continued for twelve months, one died before inquiry, three were withdrawn, and three did not disclose any grounds for reference to a tribunal.

INFECTIOUS DISEASES INTRODUCED FROM ABROAD.

The weekly reports supplied by the Ministry to port medical officers are proving of material assistance.

Plague has been absent from this country, and India has been exceptionally free from it, though Northern China had a severe epidemic, which spread to Vladivostok. There were few cases on the continent of Europe, but the disease was discovered in several parts of Australia in September, 1921. Experience continues to confirm the importance of rats and rat-fleas as carriers of infection.

A serious epidemic of cholera prevalent in the famine-stricken areas of Russia in June and July underwent an abrupt decline in August; there has been no prevalence in the rest of Europe, though in parts of Russia and in the Ukraine it seems to have again

led in 1,644 instances in the year 4,163 in the previous year, and indigenous cases were discovered against 103 and 36 in 1919 and 1920. It was found, however, that the malaria mosquito could accommodate itself to a dry year in South-Eastern England by resorting to exceptional breeding places, such as the river-Wey at Guildford and deep pools in abandoned quarry pits in Kent. The other English anophelis showed a similar adaptability, so that the problem of control requires further biological study.

Typhus fever in 1921 was almost world-wide in distribution, largely owing to repatriation and refugees. Though there had been much diminution from the estimate of 20,000,000 cases in Russia in 1919-20, yet recrudescence occurred in November, both in Russia and Poland. The disease, however, was absent from England.

Dysentery.—The number of cases of dysentery reported was 1,228, against 1,353 in 1920 and 1,657 in 1919. Most of the cases were due to relapsing amoebic dysentery among ex-service men in July, August, and September.

Trench fever was notified only among discharged soldiers, and only to the number of 13 cases, against 39 in 1920 and 99 in 1919.

VENEREAL DISEASE.

Sir George Newman records that schemes of treatment on the lines laid down by the Royal Commission of 1916 have now been instituted in 61 counties, 80 county boroughs, and the City of London, making 142 in all. The treatment centres established number 194 (151 in voluntary hospitals, 15 elsewhere, and 28 in special premises), with about 800 weekly sessions. In 120 clinics there is provision for immediate treatment of gonorrhoea. The medical staff of the clinics consists of 384 approved officers. At most of the hospital clinics some beds are available for in-patients. There are 15 hostels for receiving 259 women and girl patients, and the number treated was 770. Nine institutions take in pregnant women with venereal disease, and valuable preventive results have been achieved as to ophthalmia neonatorum and infantile syphilis. The work of 1921 consisted mainly of consolidation by improvement of methods, increase of facilities, bettering of arrangements and equipment, and changes of personnel. The difficulty in getting patients to attend long enough is mentioned, and it is said in this respect much depends on the personality and efficiency of the medical director, and on the adequacy of the premises, especially for irrigation in gonorrhoea; special premises attached to hospitals are best. Most practitioners, it is stated, fail to take advantage of the facilities provided for examination of pathological specimens, and fewer qualify themselves for obtaining free supply of salvarsan substitutes, or attend with patients for consultation. There is lack of collaboration between medical officers of health and the venereal diseases officer.

The statistics show a significant reduction in the new cases dealt with in 1921 (roughly of about 20 per cent.). In 1920 the new cases numbered 105,185, and 84,715 in 1921; on the other hand, persistence in treatment is greater. It is claimed that the clinics are proving centres of enlightenment and education, and that the majority of cases of syphilis are

rendered temporarily non-infectious; it is believed by experienced officers that the reduction in new cases is due to this cause, and that a substantial proportion of syphilitic cases are cured even according to the rigorous standard of the Ministry. Sir George Newman concludes this part of the report by a statement of his views on the still more important subject of the prevention of venereal disease, which ought not to be separated from the treatment.

MEDICAL AND SANITARY ADMINISTRATION.

The survey of port and riparian districts was continued, and conferences with local authorities were held. Medical examination of aliens continues to work smoothly. Schemes as to isolation and small-pox hospitals were a subject of inquiry, and 140 inspections were made. The Public Health (Officers) Act, 1921, gives increased security of tenure to certain whole-time medical officers of health and sanitary inspectors. A qualification is now for the first time required for sanitary inspectors outside London, and, subject to exceptions allowed by the Minister, all medical officers of Health must now hold a diploma in public health or have three years' experience of the duties of the office. In Scotland, it may be remarked, every medical officer of health, whether his area be large or small, appointed under the Public Health Act of 1897 has been required for the last quarter of a century to hold a diploma in public health.

Poor Law Medical Service.—Systematic inspection is now made, at reasonable intervals, of all institutions. This, it may be remarked, is a great advance on the position when the Royal Commission on the Poor Law issued its report; at that time medical inspection was very much subordinate to any inspection, both in amount and in authority. The treatment of the sick and the care of children under the Poor Law is receiving special attention, as are also the facilities for medical education at Poor Law institutions in the neighbourhood of medical schools. Need for improving the nursing service is noted, and for combining areas or pooling existing institutions so as to allow better classification of patients and the provision of special treatment. That also is an old recommendation.

Smoke.

Lord Newton's Committee recommended in 1921 that the Minister of Health should be empowered to act in the place of a recalcitrant local authority and to fix standards, contravention of which would raise a presumption that an offence had been committed. The Committee recommended that a housing scheme should be approved unless it contained specific provision for smokeless methods, such as were indicated in the Committee's interim report. In the book *The Smokeless City*, reviewed recently in this JOURNAL, mention was made of Lord Newton's regret that the opportunity for introduction of smokeless heating had not been taken advantage of by the Ministry, notwithstanding the Committee's recommendation.

Water Supply Shortage.—The drought of 1921 resulted in contaminated water causing a great outbreak of dysentery in the Ogmore Valley in Wales, where 700 cases occurred, one of them, fortunately, fatal. Scavenging defects, especially the dumping of city refuse in rural areas, received attention, and gratification is expressed that local authorities had to substitute direct administration for contract work in dealing with refuse. Rat extermination at great refuse tips impossible.

MEDICAL INTELLIGENCE, INVESTIGATION, AND RESEARCH.

The number of consuls and other British representatives abroad who gave information as to infectious diseases increased from 170 to 182, and nearly 5,000 dispatches were received. Information is also obtained through the international office and foreign governments.

Investigation and Research.

American types of pneumococci in this country are under observation in the Ministry's laboratories, also the influenza bacillus. Dr. Scott is endeavouring to ascertain whether any relation exists between the virulence of outbreaks of diphtheria and the type of bacillus concerned. At the vaccine lymph laboratories the results of differences in technique and new methods of preparation and storage were studied.

Auxiliary Scientific Investigation Fund.—The causes of stillbirth, encephalitis lethargica, the Schick reaction, rheumatism, and the pneumococcus were dealt with. Liaison is maintained with the Medical Research Council in respect of tuberculosis and other matters.

Statistical investigations included the charting by areas of the notifications of infectious disease, the issue of notes to districts as to undue prevalence of disease, and the summarizing of foreign statistical records. Other questions included the estimation of the prevalence of venereal disease, district mortalities of cancer, the economic effect of abolition of particular diseases, and the factors of infant mortality.

Epidemiological inquiries included one as to encephalitis lethargica, and a comprehensive report will be published shortly. The Departmental Committee on Rheumatism instituted field inquiries by the regional medical officers and insurance practitioners in various parts of the country.

International Work.

The scope of this work has already been incidentally referred to. Requests for advice on public health subjects from foreign, colonial, and home offices and the British Dominions have been complied with. For the Foreign Office Sir George Buchanan represents the Ministry on the Inter-Departmental Committee on Quarantine. In September, 1921, the League of Nations established a Health Committee with a medical director and a small staff. It has made progress in the standardization of therapeutic serums and the serological tests for syphilis. It has also arranged for epidemiological inquiry in the near East, and the League's medical section organized a conference last March in Warsaw regarding epidemics of cholera, typhus, relapsing fever, small-pox, etc., in Russia and Eastern Europe. The League appointed an epidemic commission in 1920 to help Poland and other States on the western border of Russia to combat epidemics; Britain's contribution to the cost was £50,000. The funds were exhausted at the end of 1921; an influx of refugees from Russia to Poland was followed by a spread of typhus and relapsing fever. As Sir George Newman says, in concluding his report, there are two questions—What can be done internationally to help the States west of Russia? and, What can be done to deal with the present appalling health conditions in Russia itself?

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee held on August 8th, 1922, 37 cases were considered and £477 voted to 35 applicants. The following is a summary of some of the cases relieved:

... R.C.P. who died in 1913. Applicant but owing to ill health has had to in the Nightingale's Hospital. Her only income is from the Health Insurance. Voted £18 in twelve instalments.

Daughter, aged 52, of J.S.A. and F.R.C.S. who died in 1913. Applicant was formerly a governess, but gave this up in order to look after her mother and attend to the home. Her father left her £300 and she has been living upon this, but it is nearly spent. Rent 3s. a week. Voted £8 in twelve instalments.

Widow, aged 53, of M.R.C.S. Eng. who died in 1920. Applicant has been supported by her eldest son, who has just died quite suddenly. She has had to borrow £15 for funeral and other expenses connected with his death. Her only income is £70 from the 'Widows' and Orphans' Fund and 10s. a week allowed by her son who is a clerk. The daughter is only able to support herself. Voted £15.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, K.B.E., C.B., M.S., at 11, Chandos Street, Cavendish Square, London, W.1.

THE State Hospitals Commission, which controls all the mental hospitals in New York State, has issued its thirty-second annual report. The number of patients under treatment during the year was 49,376 (an increase of 832). The recovery rate based on first admissions was 25 per cent.; on the same basis those benefited formed 55 per cent.; 3,830 died. The total cost of upkeep was 15 million dollars; over three-quarters of a million was received from paying patients. The average payment of the paying patient was about one-half the average cost of maintenance. Each institution is visited twice yearly by the Commissioners and four times by the medical inspector. Quarterly conferences are provided for by law between Commissioners and superintendents and managers; at these clinical papers are read by members of the staffs. The medical staffs number 169, an increase of 27, but there are 44 vacancies. Excluding superintendent and interns, the ratio of physicians to patients is 1 to 277. The number of alcoholic first admissions decreased from 594 in 1917 to 122 in 1920, and the rate from 6 per 100,000 of general population to 1.2. There has been some diminution in the entry of combined cases of general paralysis and cerebral syphilis, from 962 in 1918 to 874 in 1920, "probably the direct result of the campaign against venereal disease which has been waged by the Federal and State Health Departments during the past two years."

British Medical Journal.

SATURDAY, SEPTEMBER 9TH, 1922.

THE DIAGNOSIS AND TREATMENT OF SEPTIC SINUS THROMBOSIS.

THE discussion on septic sinus thrombosis in the Section of Otology at the Annual Meeting of the British Medical Association in Glasgow is reported in full in our present issue; it should be read carefully not only by those who devote themselves to the special study of diseases of the ear, but by the medical profession at large. Septic sinus thrombosis is, in the vast majority of cases, a disease of neglect, and the condition is very much more common among the poor than among the more fortunate classes. The incidence of this, as of all intracranial complications, will be greatly lessened as the true importance of aural suppuration becomes more widely recognized and its adequate treatment is more generally adopted.

In his Presidential Address on brain surgery (JOURNAL, July 29th, 1922, p. 155) Sir William Macewen reviewed the modern history of the surgical treatment of intracranial diseases, our knowledge of which—like that of all other diseases—has been gained by clinical observation, *post-mortem* investigation, and experimental research. Brain abscess and meningitis were known to the Greeks and Romans and to the mediæval surgeons; and Morgagni, early in the eighteenth century, showed clearly that intracranial suppuration was secondary to aural suppuration. Before the era of Lister occasional attempts had been made to cure intracranial suppuration by following up the track of a fistula, but the work of the modern brain surgeon, made possible by Pasteur and Lister, had to follow that of the research worker on brain function. So Macewen in 1881 followed Ferrier in 1873.

The complication of sinus suppuration was not recognized until the early years of the nineteenth century, long after brain abscess was known to arise from aural suppuration. Robert Hooper, in his *Morbid Anatomy of the Human Brain* (London, 1826), gives an illustration of suppuration in the lateral sinus, and says, in the description which accompanies the plate, that the condition had probably never before been observed. John Abercrombie, however, in *Pathological and Practical Observations on Diseases of the Brain and Spinal Cord* (Edinburgh, 1828, p. 45), gives in some detail the history of a patient suffering from this condition which he had recorded in August, 1816. Wilde and Toynbee—pioneers of aural surgery—observed cases of sinus suppuration, but without distinguishing them from other intracranial complications, and the first account of the condition in a work on general medicine was given by Lebert in 1859 (*Traité d'Anatomie Pathologique*).

Zaufal, at a medical meeting in Prague in 1880, recommended that in cases of sinus infection the internal jugular vein should be tied and the sinus opened, but his suggestion was not taken up except as a point for merely academic discussion. It remained for Arbutnot Lane in 1888 to put this idea into practice; he had at the time no knowledge of Zaufal's recommendation. He was followed by Charles Ballance, who likewise was not aware of the earlier work of Zaufal or Lane. The operation soon became generally adopted.

During the discussion at Glasgow Sir William Milligan and Mr. Lionel Colledge touched upon some important points in the diagnosis of septic sinus thrombosis. The diagnosis in a typical case is not difficult: in any case of purulent otitis media a sudden rise of

temperature, accompanied by a rigor, should always suggest the beginning of a septic sinus phlebitis. But atypical cases are not infrequent, particularly among children, and merely to await in such cases the development of the typical signs and symptoms would be disastrous. Often the aural discharge may have ceased for some considerable time, and the condition may be diagnosed as typhoid fever, pneumonia (especially a central pneumonia), pyæmia of unknown origin, or malaria. Various diagnostic tests can be employed to eliminate certain of these diseases; examination of the retina may show optic neuritis (which is present in about 30 per cent. of cases of sinus thrombosis), and a careful examination of the ear may reveal unsuspected pus and small granulations. There was general agreement in the discussion that in doubtful ear cases where there is any suspicion of sinus thrombosis it is better to operate and expose the sinus than to wait. Sir Charles Ballance well said on a former occasion in this JOURNAL (September 10th, 1921, p. 399) that persistence of disease in the temporal bone is the indication for operation; the indication for operation is not, and ought never to be, the onset of an intracranial complication. We do not await the onset of general peritonitis before removing an inflamed gall bladder, a suppurating Fallopian tube, or a diseased appendix.

In regard to the operative treatment of septic sinus thrombosis, the discussion in the Section of Otology ranged mainly around the subject of tying the jugular vein. There is a certain school of opinion—chiefly on the Continent—that ligation of the jugular vein is to be condemned unless the clot has actually reached the neck. On the other hand, certain surgeons tie the vein in all cases as a precautionary measure. The consensus of opinion at Glasgow was that the best practice lies somewhere between the two extremes. By ligating the vein the main channel of systemic infection is shut off, and free drainage is also provided for any septic material in the sigmoid sinus and the jugular bulb or vein. This procedure should be adopted when the jugular vein is obviously infected or when infection of the jugular bulb has been diagnosed; and when, after operation, it is found to be impossible to clear out the whole of the infected clot, or the sinus having been cleared, the symptoms of infection continue.

OSTEOPATHY AND CHIROPRACTIC.

THE members of the medical profession in Britain and in the United States, while they have many points in common, have at the same time different problems and different difficulties confronting them. The fight against "medical clubs," which went on for so many years in this country until it subsided into the comparative placidity of National Insurance practice, has had no counterpart in America. On the other hand, the campaign against cheap medical schools and inferior medical qualifications, in which—almost entirely through the efforts of the American Medical Association—complete victory has now, we may hope, been gained, has been unnecessary in the British Empire. One of the most urgent problems to-day in the United States is the growth of medical "cults," with the assistance of newspaper and other propaganda, and certain of those "cults" have obtained so firm a footing, even upon the medical boards of certain States, that it appears to be almost impossible to dislodge them.

From time to time exponents of American "para-medical" theories have made guerrilla warfare upon this country, and one of these sporadic raids, aided by the ever-present publicity agents and advertising experts, appears to be in progress at the present time. Some months ago a well-attended (and well-reported) meeting

was held in London where among others a gentleman (reputed to be the funniest comedian in London) made a speech explaining how osteopathy had practically saved his life. It may be useful, therefore, for British medical practitioners to have some knowledge of what the brave words "osteopathy" and "chiropractic" really mean. They will find material for this in the *Boston Medical and Surgical Journal* of March 2nd, 1922, which contained the report of a committee of the Massachusetts Medical Society, who investigated these subjects fully.

Osteopathy was founded, it is said, by a doctor of medicine, and rests upon the assumptions that the human body contains all the elements necessary for health, and that if the circulation within the body is normal these elements will maintain health. The impairment of circulation, preventing the proper supply of these elements to all parts, is considered to be the cause of disease; this impairment is attributed to the action of the vasomotor nerves, which are assumed to be affected by direct pressure from bones, muscles, or ligaments in the region of the spine, or by reflex irritation from disturbance in visceral organs or other parts of the body. The founder of the cult stated that there was no need for the vast amount of medical knowledge which had been accumulated for centuries, because it was only necessary to discover the "lesion" that was causing the disturbance in the circulation, and to correct this, when health would result. It is hardly necessary to point out that there is, of course, absolutely no experimental or other scientific evidence in support of this notion—although a so-called "research institute" in osteopathy has been established in California. It appears that some of the more educated osteopaths are now condescending enough to allow that their "theory" need not replace all medical knowledge, and in very recent osteopathic writings some use is made of general medical knowledge, especially in regard to diagnosis.

Osteopaths vary somewhat in their conception of the so-called "osteopathic lesion"; but in general they agree that the lesion consists in certain abnormalities of the muscles, ligaments, or joints, and claim that in the presence of this combination of abnormalities the "lesion" should be found at some point along the spine in practically all diseases, although there is no specificity of the lesion for different diseases in the same organ. According to this crude doctrine tumour of the kidney, nephritis, tuberculosis of the kidney, and pyelonephritis would present a similar "lesion." The osteopathic method of treatment is to endeavour by manipulations "to correct displacement of the bony surfaces, if any exist, and to relax the muscular spasm and remove the point of tenderness." It is possible, even probable, that in a certain limited number of vaguely defined conditions—chiefly in those painful backs which every medical practitioner in industrial practice knows so well and which were so common on early sick parade in the army—the osteopathic "treatment" may afford a certain relief, just as simple rubbing would; but beyond that it has not been proved to be of any value whatever in diseases of known pathology, while it is also evident that it can do serious harm in various conditions, especially when applied without a general medical knowledge.

Chiropractic, which after osteopathy appears to be the most popular of the medical cults, likewise depends upon a "theory," and this theory consists in the claim that all diseases result from pressure upon nerves as they emerge from the spinal canal. One of the leading chiropractors says in his writings that he does not want a diagnosis, the idea being that if pressure is relieved from the nerve roots health will result, irrespective of the type of disease. This notion can obviously have no experimental or other evidence to support it, either in the published chiropractic writings or elsewhere. The committee of investigation goes farther than this, for it

places on record that it is not convinced that the leaders in chiropractic are sincere, and it feels that the whole movement may be a gigantic fraud which has carried off their feet a certain number of sincere individuals. The procedure of the chiropractor is to examine the spine by palpation—and even by x rays—in order to locate "subluxation or malposition" of the vertebrae, and to profess to trace the course of the nerves for tender spots; the treatment consists in an attempt to reduce by manipulation the alleged malposition of the vertebrae. There is no evidence that this form of treatment is of any value whatever in any kind of disorder or disease. That the patient appears to receive a certain measure of comfort from the "treatment" appears probable from the tremendous growth of the cult throughout the United States, but any comfort that results must certainly be the effect of suggestion reinforced by a form of massage.

The committee of the Massachusetts Medical Society conducted its investigations in a particularly open-minded and unbiased manner. It may appear, however, to observers at a greater distance, that osteopathy and chiropractic are little more than terminological adaptations of bone-setting, with the site of operation cleverly transferred from the knee or the ankle, where results (if any) can at least be seen, to the backbone, where they cannot.

THE CONTROL OF GLYCOSURIA BY THE ISLETS OF LANGERHANS.

On July 22nd (p. 140) we gave under this heading a preliminary account of important experiments into the etiology and treatment of glycosuria which had been carried on in the Physiological Department of the University of Toronto, under the direction of Professor J. J. R. Macleod, who had long been interested in diabetes and had made many investigations with regard to it. Early observations had shown that injections of extract of the whole pancreas were of no therapeutic value in the prevention of glycosuria, and Professor Macleod was driven to the conclusion that in all probability the islets of Langerhans were essential to the control of carbohydrate metabolism. Taking advantage of the fact that ligation of the pancreatic duct produced degeneration of the acinous cells but not of the insular cells, he, with the assistance of Dr. F. G. Banting and Mr. C. H. Best, arrived at the conclusion stated in our previous note. They found that when an extract of the gland, in which the acinous cells had degenerated while the islets of Langerhans remained intact, was injected, intravenously or subcutaneously, into dogs artificially rendered glycosuric marked reduction of the percentage of sugar in the blood and the amount of sugar excreted in the urine occurred. In later experiments it was found that the pancreas of foetal calves of under five months' development did not contain proteolytic enzymes, and by extracting such foetal pancreatic tissue a highly potent preparation was obtained; the evidence supported the conclusion that the active principle was essentially the same from whatever animal it was prepared. The comment was made in our previous note that if the experimental observations proved clinically applicable to man they might provide a very important means of treating diabetes. More recently there has been published a joint paper by F. G. Banting and C. H. Best from Dr. Macleod's laboratory, by J. B. Collip from the Department of Pathological Chemistry, and by W. R. Campbell and A. A. Fletcher of the Department of Medicine of the University of Toronto, relating to results obtained in the treatment of diabetes mellitus. Collip succeeded in preparing an active extract, which retained its potency for at least one month, from normal adult ox pancreas, and this had been used by Campbell and Fletcher down to the time of the publication of the report in the treatment of seven cases of diabetes mellitus in the Toronto General Hospital. A fall in blood sugar took place in all cases, and in two,

repeatedly examined, there was a rise in the respiratory quotient, indicating carbohydrate utilization; it occurred more or less coincidentally with the attainment of a normal blood-sugar level. Decrease in the amount of sugar excreted was observed in all, and it disappeared entirely if the dose was adequate. Ketonuria also was abolished. The patients reported complete relief from the subjective symptoms of the disease and clinically an improvement was shown in the better appearance of the skin and eyes and in the increased mental and physical activity of the patients. Only one case is reported at length—that of a boy, aged 14, who had suffered from symptoms of glycosuria for a little over two years. The amount of sugar excreted in the urine diminished rapidly after the injections were begun, but rose again when the injections were withheld. When they were resumed the sugar in the urine diminished again, though not to the same extent, but the doses given were smaller. The general conclusions of the authors are that by this treatment blood sugar can be reduced—in some cases even to the normal proportion; that sugar and acetone bodies can be made to disappear from the urine; and that the respiratory quotient affords evidence of increased utilization of carbohydrates. At the same time there is a definite improvement in the general condition of the patients.

FATAL CASES OF FOOD POISONING AT LOCH MAREE.

THE Scottish Board of Health has received a preliminary report from Dr. F. Dittmar and Dr. Gerald Leighton, two of its medical officers, who investigated the recent cases of food poisoning at Loch Maree, and has issued a statement which has been published in full in many newspapers. The Board accepts the diagnosis of botulism, and states that the symptoms commonly produced in the condition occurred in the cases at Loch Maree with painful uniformity—dizziness, headache, and perhaps nausea and sickness, double vision, ptosis, dilatation and sluggish action of the pupils, paralysis of the bowel producing constipation, paralysis of the lips causing difficulty of speech, of the muscles of the throat causing difficulty in swallowing, and of the muscles of the larynx causing loss of voice. The tongue also was paralysed. Respiration was affected, so that dyspnoea occurred; ultimately paralysis of respiration and the heart produced death. The temperature remained normal or subnormal. The Board praises highly the care and consideration shown by the local medical practitioner, Dr. Knox; and by Professor Mouro and Dr. Carnegie Dickson, who happened to be staying at Loch Maree. The Board states that this is the first recorded outbreak of botulism in Great Britain and accepts the view that the symptoms were due to a toxin produced in the food before it was eaten. The *Bacillus botulinus* is an anaerobic organism, and could therefore grow in a sealed tin of preserved food, the taste and aspect of which would not be altered. The shortest interval between the ingestion of the food and the onset of symptoms in the Loch Maree cases was from sixteen to eighteen hours; the longest, we gather, was forty hours. Over a year ago the Ministry of Health and the Medical Research Council combined to make arrangements for the fuller investigation of the conditions which give rise to illness produced by the various forms of bacterial food poisoning. It was arranged that the investigation should be conducted in laboratories in the University of Bristol. The research there is directed by Dr. A. W. J. MacFadden of the Ministry of Health, in co-operation with Dr. W. G. Savage, medical officer of health for Somerset, and the work is carried out, under Dr. Savage's supervision, by Mr. P. Bruce White, B.Sc., who, according to the last report of the Medical Research Council, gives his whole time to it. Sir George Newman, Chief Medical Officer of the Ministry of Health, issued about a year ago a memorandum (C.L.1) to medical officers of health, describing the nature of the arrangements and including a memorandum by Dr. W. G. Savage with regard to the collection and transmission of samples. The Scottish Board of Health last year came into the scheme and the specimens from the Loch Maree cases were accordingly sent to Bristol. The pathological and

baacteriological investigations are being conducted there, and their results, it may be hoped, will throw light on a form of food poisoning with regard to which there is still much to be learnt. The public inquiry opened at Dingwall on Tuesday.

THE BRITISH ASSOCIATION AT HULL.

THE ninetieth annual meeting of the British Association for the Advancement of Science is being held this week and next at Hull under the presidency of Professor Sir C. S. Sherrington, G.B.E., M.D., President of the Royal Society. The President's inaugural address on "Some aspects of animal mechanism" was delivered on the evening of Wednesday, September 6th, and an account of it appears elsewhere (p. 485). The Sections, of which there are again thirteen this year, began their work on Thursday morning. In the Section of Anthropology Mr. H. J. E. Peak gave his presidential address on "The study of man." In the Section of Physiology the first day's programme included a paper by Dr. T. Ritchie Rodger on "The effect of loud noises on the cochlea," indicating the results of his investigations into the deafness of boilermakers, and giving a comparison of these with the findings of other observers who have experimented with animals exposed to loud sounds. Dr. Rodger's contention is that the changes, indicated clinically and demonstrated *post mortem*, support the theory that the cochlea is adapted for the differentiation of sound. Bearing on the same subject, Dr. G. Wilkinson described the mechanism of the cochlea with special reference to the inertia of the contained fluids. Dr. J. E. Bannen described the physiology of the gastro-intestinal tract from the radiological aspect, and Professor A. V. Hill read a paper on athletics and oxygen supply. On Friday, in the same Section, Professor E. P. Cathcart gives his presidential address on "The efficiency of man and the factors which influence it," and a joint discussion on the vitamins is being held with the Section of Agriculture. The opener of this discussion is Professor J. C. Drummond, and the other speakers include Dr. A. Seidell, Professor T. B. Wood, and Dr. J. B. Orr. At the afternoon session Professor Storm van Leeuwen is discussing experimental studies on hypersensitiveness to drug action, to be followed by a paper on the cause and treatment of bronchial asthma, hay fever, and allied conditions. The Section of Psychology opened its proceedings on Thursday morning with a paper by the President, Dr. C. S. Myers, on "Industrial psychology and the efficiency engineer"; Dr. G. H. Miles discussed breakage problems in industry and Mr. Eric Farmer "Output curves as measures of fatigue." In the afternoon Dr. C. H. Northcott discussed "Instincts and society," Miss May Collins gave an account of experiments on colour blindness, and Dr. D. Wynn Jones described the technique of "group testing." To-day (Friday) a joint discussion is being held with the Section of Education on "Psycho-analysis and the school," the principal speakers being Dr. C. W. Kimmins, Dr. Crichton Miller, Dr. Hamilton-Pearson, Dr. R. G. Gordon, and Professor T. H. Pear. A feature of this year's meeting is the daily exhibition in the Reception Room, by arrangement with the Air Ministry, of synoptic weather charts and forecasts. The weather data employed are received by wireless telegraphy from the broadcasting stations in this and other European countries. Demonstrations of the reception and of the decoding and charting of the reports are given by representatives of the Meteorological Office and of the Air Ministry. The meeting closes on September 13th; we hope to publish further notes in our next issue.

PLAGUE IN AUSTRALIA.

AN outbreak of plague which occurred in Sydney has been carefully investigated and efficiently dealt with. Infection was traced to a steamer which arrived from Brisbane in September, 1921, on which there had been a fatal case of plague. Six dead rats were found on this ship, and one of these on bacteriological examination was found to be plague infected, but the others were too putrid for examination. In the two months before the arrival of this ship rats were being continually caught and examined in the neighbourhood

of the wharf at which the ship unloaded, and these animals had never shown evidence of infection, but soon after the arrival of the ship infected rats were caught on the same wharf and in neighbouring workshops. Sixteen cases of plague subsequently developed amongst the civilian population round about the docks; by systematic study of the rat infection in the different localities in which these cases occurred it was possible in nearly every case to trace the connexion between human patient and infected rats. The details of this work are reported in the *Medical Journal of Australia*, May 20th, 1922. We wish to draw attention particularly to the administrative methods adopted to check the epidemic and the new form of antiplague serum employed in treating the cases. Dr. Armstrong states that past experience in New South Wales and Queensland has demonstrated that quarantine measures cannot secure ports from invasion without imposing on commerce such restrictions as would seriously interfere with trade. During non-epidemic periods the measures which must be insisted on are the rat-proofing of wharves and buildings and the maintenance of a detective rat-catching staff whose duties are, not to exterminate rats, but to keep going a continuous nightly trapping of the area which in a seaport town is certain to be the first attacked—namely, the water front. No city, it is argued, would be attacked by plague in which all the buildings were constructed on rat-proof principles, provided care was afterwards taken to prevent rats breeding in them. In Sydney a process of reconstruction is gradually being carried out, and much has already been accomplished in rendering storehouses and other buildings on the wharves as nearly as possible rat-proof by means of concrete flooring and slighting. When in September, 1921, the fact that Queensland had been invaded by plague was made public the rat intelligence staffs were largely increased; their operations were practically confined to the threatened area, but as the epizootic extended the disposition of the staffs was modified from time to time. Wherever a plague rat was found the premises were immediately quarantined and disinfested. The quarantine consisted in closing up the premises so as to prevent the escape of rats, and forbidding access to the public until the process of disinfestation was completed. This process, which consisted in the destruction of rats and fleas, took several days or a few hours according to the method employed; meanwhile an area comprising several street blocks around the infected premises was intensively searched by the official staff for rats, which were poisoned and trapped. The best method of disinfestation was found to be fumigation with hydrocyanic acid gas; the process is rapid, and kills both rats and fleas. Control rats in cages and fleas in test tubes were buried deeply amongst the goods in the warehouse, and after fumigation was completed the cages uncovered to see if the rats and fleas had been killed. The other method which sometimes had to be resorted to was the turning over of all the stock and movable materials by a gang of workmen and the destruction of rats as discovered. This process took several days, and owing to the survival of the fleas was not so efficacious, but it had to be employed where the hydrocyanic acid gas might possibly reach human beings. Whichever method was used the premises were not released from quarantine until all defects in the buildings had been made good by the owner and rat holes filled up, basements concreted, and the premises put into rat-proof condition. The antiplague serum used for the treatment of the hospital cases was prepared in Sydney by Dr. Burton Bradley, who used a modification of Yersin's method, horses being immunized by dead, and later by living, cultures of virulent plague bacilli. Every plague patient admitted to hospital received the antiplague serum immediately; the results are described as very satisfactory. The total mortality of cases in the outbreak was 25 per cent.; amongst patients admitted to hospital and treated with serum it was 15.4 per cent. In the opinion of the medical officers who had experience of the plague epidemic of 1900-1909 the type of disease in the present outbreak was of equal severity; the mortality of the patients treated with the serum employed at that time was 24 per cent.

PASTEUR COMMEMORATION FUND.

Mr. A. CHASTON CHAPMAN, F.R.S., hon. treasurer (in this country) of the Pasteur Commemoration Fund, writes to inform us that a sum of £848 14s. 6d. has been subscribed to this fund, in addition to sums which had previously been sent to Franco in response to earlier and direct appeals. In accordance with a resolution passed at a recent meeting of the Pasteur Commemoration Committee, presided over by Sir Charles Sherrington, F.R.S., a draft for the above amount is being forwarded to Monsieur Héring, the general treasurer, at Strasbourg, with an intimation that should the amount prove more than the French Committee desires to expend upon the monument the excess should be devoted to some other form of permanent memorial of Pasteur in the University of Strasbourg. We observe that the list of subscribers to the fund includes the names of many well-known firms of brewers, testifying to the debt owed to Pasteur by the brewing industry. Among the individual subscribers is Dr. Horace T. Brown, F.R.S., whose researches into the problems of fermentation, begun more than half a century ago under the inspiration of Pasteur, did so much to apply the methods of science to the art of brewing. The great influence exercised by the pioneers of scientific brewing upon the development of the science of bacteriology in the sixties, seventies, and eighties of the last century is apt to be forgotten. Medicine and surgery, and science at large, owe much to the fermentation industries.¹

THE NATIONAL MILK CONFERENCE.

A NATIONAL Milk Conference has been convened by the National Clean Milk Society, with the support of a number of other organizations interested in public hygiene, milk production, and the breeding of cattle. The representative appointed by the Council of the British Medical Association is Dr. T. W. H. Garstang, and among the other public bodies represented are the County Councils' Association, the Society of Medical Officers of Health, the Royal Institute of Public Health, the Royal Sanitary Institute, the National Association for the Prevention of Infant Mortality, and the Veterinary Medical Association. The conference will be held in the Council Chamber of the Guildhall, London, on Monday, Tuesday, and Wednesday, October 16th, 17th, and 18th, from 10 a.m. to 1 p.m. and from 2.30 to 5.30 p.m. each day. The President, Viscount Astor, will deliver his inaugural address at the opening session on Monday morning, October 16th, and Sir Arthur Griffith-Boscawen, Minister of Agriculture, will then take the chair. At the afternoon session, under the chairmanship of Mr. Wilfred Buckley, Sir Stewart Stockman will read a paper on "Contagious abortion and other diseases of cattle," and Dr. Stenhouse Williams will open a discussion on the production of clean milk. The morning session of Tuesday, with Sir Alfred Mond, Minister of Health, in the chair, will be devoted to discussions on bovine tuberculosis and its relation to man, opened by Drs. A. Stanley Griffith and Nathan Raw, and on tuberculin tests, introduced by Captain S. R. Douglas, I.M.S. (ret.), F.R.S. The chairman at the afternoon session will be Viscount Elveden. On Wednesday morning, with Sir Walter Morley Fletcher in the chair, a debate on pasteurization and other methods of treating milk will be opened by Professor Georges Dreyer, Dr. Charles North of New York, and Dr. Eric Pritchard. The chairman of the afternoon session will be Sir George Newman, when discussions on the food value of milk and its care in the home will be introduced by Dr. Robert Hutchison and Dr. Leonard Hill, and on education of the public and of the dairy industry in regard to milk by Sir Daniel Hall and Professor H. R. Kenwood. All applications for membership or inquiries for further particulars should be addressed to Miss H. M. Willans, honorary secretary, National Milk Conference, 3, Bedford Square, London, W.C.1.

THE EMPLOYMENT OF THE TUBERCULOUS.

THE Glasgow Health Department has issued a valuable report on the employment of the tuberculous. It has been prepared by Drs. A. S. M. Macgregor and John A. Wilson, two of the officers of the department, and records the results of an inquiry into the various types of tuberculous patients with reference to their training and employment. It has a preface by Dr. A. K. Chalmers, the chief medical officer of health. The report investigates the suitability and practicability of the training colony and village settlement system for ex-service men who have the initial advantage of a supplementary source of income as pensioners, and who therefore seem *prima facie* well fitted for either colony or village settlement. The cases passed under review numbered 785, and the way in which, for one sufficient reason or another, the great bulk of them were held to be unsuitable makes a very interesting story. As being only doubtfully tuberculous on clinical observation and x-ray examination, 122 were rejected. Of the remaining 663, in 49 the disease was arrested, in 325 quiescent, and in 289 active, a high standard being applied in making the classification. On the Turban scale 26 per cent. fell into stage I, 48 per cent. into stage II, and the remaining 26 per cent. into stage III. Complications and concurrent affections, especially bronchitis, existed in 161 patients, the great majority of whom were therefore unfit for training in a suitable occupation, and the total cases regarded as medically ineligible were 230. This left 433 for consideration. Most of the cases had been under institutional treatment or otherwise under observation, and the careless, indifferent, or worthless types could, in that way, be separated out. The number rejected or reserved for further consideration on this ground was 191. This left 242. To them there was applied the standard of the Inter-Departmental Committee—namely, training for reintroduction into employment, and of the 242 only 127 could be regarded as eligible. Of these, 110 were already engaged in occupations, many of which were not at all unsuitable—gardeners, tram drivers, travellers, postmen, and the like—while among certain others the exact conditions of employment would be the criterion of suitability. Family ties were an important consideration in making a man stick to his own trade rather than undergo training for a better one. In short, the investigation has led Drs. Macgregor and Wilson to attach weight to the experience of Dr. Noel Bardswell in a report to the London County Council; he stated that of 160 men who passed through the training centres in 1918-21, only nine were still at their newly acquired calling at Christmas, 1921, the remainder of those still alive living on their pensions and being in a state of unemployment. These are anything but encouraging facts. The reporters put the practical question which is being applied to all public health problems in the present circumstances of this country. As to a village settlement they ask, "Would the preventive results be commensurate with the cost?" and they cautiously reply, "The village settlement as a method of treating the individual is admirable; as a public health investment it might not justify its cost."

DR. STEPHEN SMITH.

THE Nestor of Public Health in America has passed away while only a few weeks short of the hundred years which he regarded as "the birthright of every child fully developed." Apparently he had not been very healthy in his early years, as he recorded that, on medical advice, he adopted the profession of medicine "as a preventive measure against the recurrence of a form of indigestion of which I had been a victim from childhood"; and he adds, writing last year, "To that advice I attribute my activities in middle life and the comparatively comfortable age to which I have attained." Indeed, more than half a century ago Dr. Stephen Smith was practising and preaching that combination of conservation of individual health and improvement of environment which is the twofold ideal of the sanitarian to-day. As regards the

individual, he set forth ten maxims for longevity, thus: "Eat hardly any meat; drink lots of milk—if it disagrees with you drink more; take a ten or fifteen minutes' nap after luncheon and dinner; sleep ten hours; sleep outdoors when the weather permits; don't smoke; don't eat sweets; take no alcoholic or other stimulants; avoid the easy chair—absence of work is the first step to the grave; finally, just be natural, quit all foolishness." He often said, epigrammatically, "Every man who dies before a hundred practically speaking dies by his own knife and fork." Sometimes a man who has professed to teach the science of longevity has demonstrated in his own death the failure of his scheme; it was not so with Dr. Stephen Smith. So much for the individual. As to environment, he showed in his contribution to the Jubilee Historical Volume of the American Public Health Association (whose first president he had been) that he was both pioneer and leader in the public health movement which began in the United States in the sixties and seventies of last century. His death will be deeply regretted throughout the American continent, but of few men can it be said that, before the end came, life's programme had been carried out as it was in the case of Dr. Stephen Smith. On this side of the Atlantic the sympathy of the public health service in particular will go out to the American Public Health Association in the loss of its doyen sanitarian and first president.

THE FUTURE OF MEDICAL PERIODICALS.

IN the capacity of English correspondent to the journal of the Norwegian Medical Association Dr. Claude Lillingston¹ contributed early this year an essay on the present and future of medical journalism, to which some reference may now be opportune. His main thesis is concerned with the unwieldiness and vain repetitions of medical writings; for every paper containing information both important and new there are, he says, very many that possess neither of these virtues. With journals as with mammals fatness is apt to lead to sterility, and with the growing volume of publications it is becoming increasingly difficult to discover a discovery. Illustrative examples of this state of affairs are given. How, he asks, can the 99 per cent. irrelevant publications be suppressed and the less than 1 per cent. new and valuable information be given the prominence it deserves? The solution which he considers most promising is the development of the abstract—the severely pruned and edited summary of an original article. He finds most abstracts at present dull and lifeless; but as their importance becomes more generally appreciated the work expended on them should, he thinks, improve. An abstract may be made by the simple expedient of "lifting" whole chunks out of the beginning and end of a paper, and adding any sentence the author may have been obliging enough to print in italics. Or the abstractor may read through the original carefully once or twice, pick the whole structure to pieces, and then build up a faithful replica of the original in miniature. Dr. Lillingston suggests that publications such as this journal's weekly *Epitome*, and the monthly publications *Medical Science* and the *Medical Review*, should do something to meet the difficulties discussed, and the tripartite scheme of *Tubercle*, which prints (1) original articles, (2) abstracts, and (3) a bibliography giving only the titles and references of original articles on tuberculosis, ought to satisfy the digestive capacity of every reader in this particular field. But it is doubtful if Dr. Lillingston will prove correct in his forecast that the journal which devotes its pages to abstracts alone will become the generally acknowledged court of final appeal towards which publication *in extenso* elsewhere will be but a preliminary step. Time was when the prophecy was confidently made that man would reduce his dietary to a few compressed tablets a day, but he still prefers his food in bulk; and, however conscientious an abstractor may be, his digest is apt to lack literary vitamins and other intangible, though valuable, properties possessed by the original article.

TREATMENT AND PREVENTION OF DIPHTHERIA.

A SHORT memorandum on diphtheria recently issued by the Ministry of Health deals with the supply and administration of diphtheria antitoxin, the use of the Schick test, and methods of active immunization for the prevention of diphtheria. In August, 1910, the Diphtheria Antitoxin Order of the Local Government Board authorized local authorities to provide medical practitioners with antitoxic serum for use in the prevention and treatment of diphtheria; the Order required that the arrangements should be made under the supervision of the medical officer of health, and should secure that the medical practitioner who needs a supply of antitoxin from the local authority shall always obtain it without delay. In every case where a provisional diagnosis has been made a dose of at least 8,000 units should be injected as early as possible, without waiting for bacteriological confirmation of the diagnosis. The injection may be subcutaneous or intramuscular, but the latter is to be preferred, as absorption is more rapid. Although no stereotyped procedure can be laid down for subsequent doses it is stated that the experience of the Metropolitan Asylums Board hospitals is that when, in a case seen early in the attack, an initial dose of 8,000 units is followed by definite improvement at the end of about twelve hours further administration of antitoxin is unnecessary. Should there be no evidence of improvement, or if it is clear that the disease is advancing, a second dose of similar magnitude should be given, followed by a further dose if no distinct improvement occurs. Diphtheria antitoxin should not be administered to a person not presenting local signs or symptoms of diphtheria in whose throat or nose the diphtheria bacillus has been found, for there is no evidence that antitoxin has any effect in causing the disappearance of diphtheria bacilli from a chronic carrier. Some abnormality of the throat is often present in such persistent carriers, and this should receive special attention and treatment. A prophylactic dose is rarely necessary for "contacts" if they can be kept under daily observation and antitoxin administered at short notice if symptoms develop. This is especially true of adults. Should a prophylactic dose be deemed necessary it should be 500 to 1,000 units. When the Ministry of Health Report on the Schick Test was published it was considered at length in this JOURNAL (December 10th, 1921, p. 994), and it may be sufficient to point out at present that its object is to determine whether or not healthy persons possess a natural antitoxic immunity, for it has been found by experience that the blood of individuals who possess a natural immunity to the disease contains per cubic centimetre not less than 1/30 unit of antitoxin. To determine whether or not this is present 0.2 c.c.m. of a freshly made dilution of standardized diphtheria toxin is injected into the skin, and as a control a similar amount of the same solution, previously heated to destroy the toxin, is also injected intradermally into the opposite arm. If the reaction is positive, indicating a susceptible individual, a circular area of more or less deep red colour appears round about the site of injection in twenty-four hours, while no change occurs on the control arm. This is due to the irritant action of the toxin acting on tissue cells not protected by antitoxin, and indicates that little or no antitoxin is present in the patient's blood, and in consequence susceptibility to diphtheria exists. If there is no change at the site of inoculation the test is negative, indicating immunity to diphtheria. The object of injecting heated toxin into the other arm is to make sure that any inflammatory reaction that appears is not due to a non-specific susceptibility to foreign protein; such a non-specific reaction usually reaches its height in twenty-four hours, and may have faded by the fourth day, whereas a true positive reaction is often most pronounced after ninety-six hours have elapsed. The Schick test has many useful practical applications to diphtheria prevention, more particularly in the case of nurses and others specially exposed to risk of diphtheria infection, and on the occurrence of diphtheria in residential schools and institutions. In susceptible individuals showing a positive Schick reaction

active immunity may be induced by inoculations of "toxin-antitoxin," this being a carefully standardized mixture of diphtheria toxin and protective serum. Three separate inoculations of 1 c.c.m. should be given at intervals of a week; in adults such injections may be followed by a local reaction or mild constitutional disturbance. The immunity takes some time to develop to its maximum, which is reached in a period of from two to six months, and has been shown to persist for more than six years. Such active immunization is especially valuable for protecting susceptible individuals who are likely to be exposed to infection; because of the slow development of the immunity the work of active immunization should be carried out in interepidemic periods.

THE CAMBRIDGE CHAIR OF PATHOLOGY.

The Chair of Pathology in the University of Cambridge, vacant since the death of Sir German-Sims Woodhead at the end of last December, has now been filled by the election of Henry Roy Dean, M.D., F.R.C.P., Professor of Pathology in the University of Manchester and Pathologist to the Manchester Royal Infirmary. The Chair of Pathology at Cambridge was established in 1884. The first holder was Charles Smart Roy, who died in 1897; the next was A. A. Kanthack, who died at the end of 1893, and was succeeded by Sims Woodhead. As Sir Clifford Allbutt said in his introductory note to the *Handbook* of the last Cambridge meeting of the British Medical Association, this professorship "was founded for Roy, a brilliant leader, early stricken down by ill health; as soon afterwards was his no less brilliant successor, Kanthack." The fourth holder was born in 1879, and has had a distinguished career as student, investigator, and teacher. Educated at Sherborne and at New College, Oxford, where he won first-class honours in the Natural Science School in 1900, he was later elected a Senior Demy of Magdalen College. He entered St. Thomas's Hospital with a university scholarship, and afterwards held the posts of medical registrar and resident assistant physician. Tenure of a Radcliffe travelling fellowship was followed in 1912 by Dr. Dean's appointment to the Chair of Pathology and Bacteriology in the University of Sheffield; this he resigned four years later to take up the corresponding post in Manchester. A great opportunity, we believe, awaits him at Cambridge.

THE MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS.

We publish in the SUPPLEMENT this week, at the request of the Registrar of the General Medical Council, a list of medical practitioners who have not replied to his inquiries as to the accuracy of their addresses. The list includes all untraceable names from A to G in the body of the *Medical Register*, as it is only this section which has come under review in the present year. Any medical practitioner who finds his or her name included in this list should communicate immediately with the Registrar of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, of the Scottish Branch Council, 20, Queen Street, Edinburgh, or the Irish Branch Council, 35, Dawson Street, Dublin, according to the part of the British Isles in which the name was registered. Since this list was prepared many further inquiries have been sent out, but every practitioner whose name appears in the list would do well to communicate with the Registrar.

We regret to announce the sudden death on September 5th, while on a visit to Dornoch, of Sir Charles Ryall, C.B.E., senior surgeon to the Cancer Hospital, and a member of the Council of the Royal College of Surgeons of England.

The office of the *Medical History of the War* is being moved to-day from Stanhope House, Kean Street, Drury Lane, to Imperial House, Tothill Street, Westminster, S.W.1, where it will be opened for work on September 11th, in Rooms 79C, 20, 81, and 83, on the fifth floor.

ANIMAL MECHANISM.

SIR CHARLES SHERRINGTON'S PRESIDENTIAL ADDRESS TO THE BRITISH ASSOCIATION.

At the inaugural general session of the ninetieth annual meeting of the British Association for the Advancement of Science, which opened at Hull in the City Hall on September 6th, Sir Charles Scott Sherrington, G.B.E., M.D., P.R.S., gave his presidential address on "Some aspects of animal mechanism."

He began by observing that once a year, at the gathering of the British Association, science tried to remove the reproach that it lived too much to itself. These occasions gave the opportunity of talking in wide gatherings about scientific questions and findings. The questions most difficult to answer were often those that could be quite briefly put. Thus, "Is the living organism a machine?" "Is life the running of a mechanism?" The answer certainly could not be stated as shortly as the question, but he proposed to examine some of the points raised.

Mechanical Adjustments in the Human Body.

It might be thought that the problem was presented at its simplest in the simplest forms of life; yet it was in certain aspects more seizable in complex animals.

Our own body is full of exquisite mechanism. Many exemplifications could be chosen. There is the mechanism by which the general complex internal medium, the blood, is kept relatively constant in its chemical reaction, despite the variety of the food replenishing it and the fluctuating draft from and input into it from various organs and tissues. In this mechanism the kidney cells and the lung cells form two of the main submechanisms. And one part of the latter is the delicate mechanism linking the condition of the air at the bottom of the lungs with that particular part of the nervous system which manages the ventilation of the lungs. On that ventilation depends the proper respiratory condition of the blood. The nervous centre which manages the rhythmic breathing of the chest is so responsive to the respiratory state of the blood supplied to itself that, as shown by Drs. Baldwin and Priestley some years ago, the very slightest increase in the partial pressure of carbon dioxide at the bottom of the lungs at once suitably increases the ventilation of the chest. And dovetailed in with this mechanism is a farther one working for adjustment in the lung is stretched by each inbreath the degree to which inspiration shall fill them ere there ensue the opposite movement of outbreath. All this regulation, although the nervous system takes part in it, is a mechanism outside our consciousness. Part of it is operated chemically; part of it is reflex reaction to a stimulus of mechanical kind, though as such unperceived.

The President then turned to another instance of mechanical adjustment, mainly nervous. The postural action of muscles was produced by nerve centres forming a system more or less their own. Maintenance of the erect position involved due co-operation of many separate muscles in many parts. Even in the absence of those portions of the brain to which consciousness was adjunct the lower nerve centres successfully brought about and maintained the co-operation of muscles resulting in the erect posture. He showed how the various harmonies of posture were provided by mere reflex action.

Problems of Animal Mechanism.

All these delicate adjustments and reactions worked involuntarily as a pure mechanism, their analysis being owed mainly to Magnus and de Kleijn of Utrecht.

True, he continued, in such a glimpse of mechanism what we see mainly is how the machinery starts and what finally comes out of it; the intermediate elements of the process we know less of. Each insight into mechanism reveals more mechanism still to know. Thus, hardly was the animal's energy balance in its bearing upon food intake shown comfortably to conform with thermodynamics than came evidence of the so-called "vitamins." Unsuspected influence on nutrition by elements of diet taken in quantities so small as to make their mere caloric value quite negligible; thus, for the growing rat, to quote Professor Harden, a quantity of vitamin A of the order of 1/300 milligram a day. Again, as regards sex determination, the valued discovery of a visible distinction between the nuclear threads of male and female brings the further complexity that in such cases sex extends throughout the whole body to every dividing cell. Again, the association of hereditary unit-factors; such as body colour or shape of wing, to visible details in the segmenting nucleus seemed to simplify by epitomizing. But further insight tends to trace the inherited unit character not to the chromosome itself, but to balance of action between the chromosome group. As with the atom in this heroic age of physicists, the elementary unit assumed simply proves, under further analysis, to be itself complex. Analysis opens a vista of

further analysis required. Knowledge of muscle contraction has, from the work of Fletcher and Hopkins on to Hill, Martree, Moyerhof, and others, advanced recently more than in many decades heretofore. The engineer would find it difficult to make a motor machine out of white of egg, some dissolved salts, and thin membrane. Yet this practically is what Nature has done in muscle; and obtained a machine of high mechanical efficiency. Perhaps human ingenuity can learn from it. One feature in the device is alternate development and removal of acidity. The cycle of contraction and relaxation lies traced to the production of lactic acid from glycogen and its neutralization chiefly by alkaline proteins; and physically to an admirably direct transition from chemical to mechanical effect. What new steps of mechanism all this now opens! To arrive at one goal is to start for others.

Nerve Regeneration.

But knowledge, while making for complexity, made also for simplification, and there seemed promise of simplification in regard to the mechanism of reflex action. Fuller knowledge of the mechanism of the nervous impulse, many of whose physical properties were now known, was leading to a view that nervous function throughout the system was simpler than had formerly been thought. Yet for some aspects of nervous mechanism the nervous impulse offered little or no clue; for instance, the regeneration of the nerve fibre after severance.

Can we, he asked, trace the causes of this beneficent yet so unaccountable reaction? How is it that severance can start the nerve regrowing? How does the nerve fibre find its lost muscle microscopically miles away? What is the mechanism that drives and guides it? Is it a chemotaxis like that of the amoeboid in the botanical experiment drawn towards the focus of the dissolved malleic acid? If so, there must be a marvelously arranged play of intricate sequences of chemically attractive and repellent substances dissolved suitably point to point along the tissue. It has recently been reported that the nerve fibre growing from a nerve cell in a nutrient field of graded electrical potential grows strictly by the axis of the gradient. Some argue for the existence of such potential gradients in the growing organism. Certainly nerve regeneration seems a return to the original phase of growth, and pieces of adult tissue removed from the body to artificial nutrient media in the laboratory take on vigorous growth. Professor Champy describes how epithelium that in the body is not growing when thus removed starts growing. If freed from all fibrous tissue its cells not only germinate, but, as they do so, lose their adult specialization. In nerve regeneration the nerve-sheath cells, and to some extent the muscle cells which have lost their nerve fibre, lose likewise their specialized form, and regain it only after touch with the nerve cell has been re-established. So similarly epithelium and its connective tissue cultivated outside the body together both grow and both retain their specialization. All seems to argue that the mutual touch between the several cells of the body is decisive of much in their individual shaping and destiny. The severance of a nerve fibre is an instance of the dislocation of such a touch.

Nevertheless, marvellous though nerve regeneration was, its mechanism seemed blind. Its vehemence was just as great after amputation, when the parts lost could, of course, never be re-reached. Its blindness was sadly evident in the suffering caused by the useless nerve sprouts entangled in the scar of a healing or healed limb-stump. There was a great difference between growth of such regeneration and the growth impulse in pieces of tissue isolated from the body and grown in media outside. New ground was being broken in the experimental control of tissue growth. The following of all clues of difference between the mechanism of malignant growth and of normal growth was fraught with importance which might be practical as well as theoretical.

The regenerating nerve, he continued, rebuilds to a plan that spells for future function. But throughout all its steps prior to the actual reaching the muscle or skin no actual performance of nerve-function can take place. What is constructed is functionally useless until the whole is complete. So similarly with much of the construction of the embryo in the womb for purposes of a different life after emergence from the womb; with the construction of the butterfly's wing within the chrysalis for future flight; of the lung for air-breathing after birth; of the reflex contraction in the foetal child of the eyelids to protect the eye long before the two eyelids have been separated, let alone ere hurt or even light can reach it. The nervous system in its repair, as in its original growth, shows us a mechanism working through phases of non-functioning preparation in order to forestall and meet a future function. It is a mechanism again whose seeming prescience is to be set its fallibility and its limitations. The how of its working is at present chiefly traceable to us in the steps of its results rather than in comprehension of its intimate reactions; as to its mechanism, perhaps the point of chief import for us here is that those who are closest students of it still regard it as a mechanism. But if to know be to know the causes we must confess to want of knowledge of how its mechanism is contrived.

Mind and Body.

At this point the President turned to consider briefly the action of the mind upon bodily mechanism, mentioning that his theme had been partly chosen at the instance of the

late Dr. Rivers, who, as a biologist, viewed mind as a biological factor. While mental actions could not at present be dealt with in terms of nervous actions, or *vice versa*, something might be gained by considering certain points of contact between the two. His first instance was the so-called expression of the emotions.

The mental reaction of an emotion is accompanied by a nervous discharge which is more or less characteristic for each several type of emotion, so that the emotion can be read from its bodily expression. This nervous discharge is involuntary, and can affect organs, such as the heart, which the will cannot reach. Then there is the circumstance that the peculiar ways and tricks of the nervous machinery as revealed to us in the study of pure reflex reactions repeat themselves obviously in the working of the machinery to which mental actions are adjunct. The phenomenon of fatigue is common to both, and imposes similar disabilities on both. Nervous exhaustion and mental exhaustion mingle. Then, as offset against this disability, there exists in both the amenability to habit formation, mere repetition within limits rendering a reaction easier and readier. Then, and akin to this, is the oft-remarked trend in both for a reaction to leave behind itself a trace, an engram, a memory, the reflex engram, and the mental memory.

Taking examples from various fields the President showed how the features of nervous and mental working resembled each other over and over again. Was it, he asked, more metaphorical to speak of mental attitudes as well as bodily? Or was it more analogy to liken the warped attitude of the mind in a psychoneurotic sufferer to the warped attitude of the body constrained by an internal potential pain? Yet all this similarity did but render more succinct the old enigma as to the nexus between nerve impulse and mental event. The practical man had to accept nervous function as a condition for mental function without breaking his heart over ignorance of their connexion. The doctor, the lawyer, and the scientist accepted it. Decade by decade the connexion became more ascertained between certain mental performances and certain cerebral regions. The cortex of the forebrain was the main seat of the mind. That cortex, with its twin halves corresponding to the two side-halves of the body, was really a single organ knitting those halves together by a still further knitting together of the nervous system itself. From very small beginnings this great integrating system had become steadily a larger and larger feature of the nervous system, until in adult man the whole rest of the system was relatively dwarfed by it. Physiologically the supreme development of the brain, psychologically the mental powers attaching thereto, seemed to represent to the biologist the very culmination of the integration of the animal mechanism. Moreover, the mental attributes of the nervous system did not stop at the individual; from individuals they integrated communities. That this integration was still developing was obvious from the whole force of human pre-history and history.

The Living Creature a Unity.

In concluding his address Sir Charles Sherrington observed that in some of its aspects animal life revealed mechanism the how of which, despite many gaps in knowledge, was fairly explicable. Of some processes of the living body it might reasonably be expected that further application of physics and chemistry would yield a competent key. But other aspects of animal mechanism still passed comprehension, and the how of the mind's connexion with its bodily place seemed utterly enigma. The lesson nevertheless appeared to be that despite great differences of difficulty in understanding different aspects of animal life it was as a single whole that the animal (and the plant, too) must finally be envisaged. For the living creature was fundamentally a unity, and if for purposes of study it had to be split into part-aspects and part-mechanisms that separation was artificial. To try to comprehend the how of the living creature as a whole was one of the great privileges of the human intellect.

The problem is ambitious, but its importance and its reward are all the greater if we seize and we attempt the full width of its scope. In the biological synthesis of the individual it regards a mind. It includes examination of man himself as acting under a biological trend and process which is combining individuals into a biological organization, a social organism surely new in the history of the planet. For this biological trend and process is constructing a social organism whose cohesion depends mainly on a property developed so specifically in man as to be, broadly speaking, his alone, namely, a mind actuated by instincts but instrumented with reason. Man, often Nature's rebel (as Sir Ray Lankester has luminously said), can, viewing this great supra-individual process, shape even as individual his course conformably with it, feeling that in this instance to rebel would be to sink lower rather than to continue his own evolution upward.

England and Wales.

METROPOLITAN ASYLUMS BOARD.

THE report of the Metropolitan Asylums Board for the year ending May 31st, 1922,¹ shows that the Board has had an exceedingly busy time. Into its fever wards in 1921 there were admitted 47,859 cases, against 35,916 in 1920 and 21,962 in 1919. The lowest number under treatment during the year was 5,423 (on September 3rd), and the highest 9,599 (on November 8th). The autumn and winter of 1920-21 had brought the biggest epidemic up to that time experienced in the history of the Board, but it was much exceeded in 1921-22. In fact, the minimum on September 3rd exceeded the maximum of nineteen of the last twenty-five years. The maximum on November 8th was composed of 6,277 cases of scarlet fever, 3,025 diphtheria, 23 of enteric fever, 196 of tuberculosis, and 78 of other diseases. It was only the river ambulance service which made it practicable to deal with those large numbers. As regards scarlet fever, after a conference with the Ministry of Health and the metropolitan medical officers of health, it was arranged that applications for admission would be made in the first instance to these officers, who would advise the Board as to the most urgent cases, preference being given to the poorer and more crowded districts, especially to cases from homes where there was unemployment. This arrangement lasted from October 25th to December 10th, when the need for it ceased. Every case of diphtheria was admitted without the postponement of a single case over a single night.

Experience of cross infection has shown that when scarlet fever, diphtheria, and measles have prevailed simultaneously, 25 per cent. of the total accommodation of the "acute hospitals" should be available for isolation, and the Board has taken special steps to that end. The fatality rate from scarlet fever was only 1.03 per cent., from diphtheria it was 8.25 per cent., from measles 8.44 per cent., and from enteric fever 18.18 per cent. Medical instruction in fever was given to 487 students, and in hospital administration for the diploma in public health to 81.

The admissions to St. Margaret's Hospital for ophthalmia neonatorum were 121 mothers and 213 babies. For ear discharges Mr. T. B. Layton, F.R.C.S., was appointed otologist in 1920, and a special report which he has made is printed in full as an appendix to the Board's report. Of venereal disease 136 cases were admitted to the Sheffield Street Hospital and 60 were treated at the Thavies Inn Infirmary. For influenza pneumonia two wards were allocated at each of the nine town hospitals, with a total provision of 150 beds, which was found more than sufficient.

Of tuberculosis there were under treatment at the middle of the year 1,906 cases (756 adults and 1,150 children). The institutional accommodation for different classes of cases is stated to be 2,138 beds in all, of which 1,261 are for children and 877 for adults. Of the 877 there are 598 for males and 279 for females. For surgical tuberculosis there are 164 adult beds, and for pulmonary 713: of the latter 321 are for advanced cases and 392 for sanatorium cases. Special provision has been made at Queen Mary's Hospital, Carshalton, for the treatment of surgical tuberculosis in childhood by direct sunlight. For change of air and scene suitable cases can be sent from Carshalton to the seaside home near Littlehampton. At Princess Mary's Hospital at Margate of 271 beds 200 are now in verandas. For surgical tuberculosis in adults a hospital of 164 beds has been equipped at Lowestoft.

Part III of the Report consists of a copy of the statement submitted by the Board to the Royal Commission on London Government. It is naturally an *ex parte* document in support of the Board's own existence as against the views of the London County Council. The Board's presentation of its case is moderate and well argued, and is just such a submission as cannot fail to receive very careful consideration from a Royal Commission. The following is the summary of conclusions given at the end of the statement:

- (i) That the interests of efficiency and economy will best be served by making the fewest possible changes in the machinery of local government for some time to come;
- (ii) That the Board should be authorized by one authority the whole of the area for the present County.

¹ Metropolitan Asylums Board: Annual Report for the Year 1921-22. Published from the Office of the Board, Victoria Embankment, E.C.4. (Pp. 178. 5s.)

(iii) That the scheme propounded by the London County Council whether regarded as a whole or so far as it proposes to give any additional administrative work to the Council depends upon—

(a) The devolution upon the local authorities of administrative duties in connexion with education, the setting up of an education department under each local authority, and as a necessary consequence

(b) The reorganization of the boundaries of the local authorities, both of the existing metropolitan borough councils and of the authorities in the area proposed to be added to London, and their substantial reduction in numbers.

(iv) That the proposed devolution is undesirable in itself, and would be costly in working; and even if carried out to the fullest possible extent would not make room for all the additional work which the Council propose to acquire.

(v) That the area proposed for Greater London (taking, for example, the Metropolitan Police area—the smallest so far suggested) cannot be regarded as constituting a "town" for purposes of local government, but would be a province, and that an entirely new form of local government would have to be devised for it.

(vi) That so far as the work of the Metropolitan Asylums Board is concerned the changes immediately desirable are—

(a) The representation upon it of the metropolitan borough councils and the London County Council;

(b) The transfer to it of the mental hospitals now managed by the London County Council and of any other institutions which it may be decided to centralize.

(vii) That if further changes are eventually decided upon the setting up of a central Poor Law authority or of a board of public health should be considered.

Scotland.

THE CENSUS OF SCOTLAND, 1921.

County of Aberdeen.

THE county census reports forming part of vol. i of the report on the thirtieth census of Scotland are being issued separately in alphabetical order; so, following the reports of the four great towns (BRITISH MEDICAL JOURNAL for August 26th, p. 399), Aberdeen is the first county to be dealt with.¹ It is amongst the largest and most important, and outside the city of Aberdeen had a population in 1921 of 153,392. Compared with 1911, this is a decrease of 4 per cent., made up of 4,179 males and 2,143 females, totalling 6,322. The highest population recorded was in 1881, when it was 162,801. The area of the county is 1,255,652 acres, so that there are approximately 12 persons per 100 acres. But the county, exclusive of the city, has various burghs, and the burghal population is 1,017 per 100 acres, whilst the non-burghal area averages only 9 per 100 acres. Such figures, it may be noted, have a bearing on the question of medical attendance and mileage allowances in rural districts. In the Deeside district there are only 3 persons per 100 acres, and in the Alford district 5. On a parish basis (some parishes include burghs) there are extreme variations in density. Indeed the term "density" is wisely avoided in the report; "sparsity" would usually be more applicable, but the census confines itself to the phrase per "100 acres." In Fraserburgh parish there are 196 persons per 100 acres, in Peterhead 176, in Inverurie 87 (all these having burghs); at the other extreme, Crathie and Bracmar parishes have only one person per 100 acres, Glenbuchat and Strathdon 2, and several others 3 and 4 persons.

Sex and Age.—The ratio of females to males in the county (excluding the city) was 108.4 to 100, as against 105.3 to 100 in 1911. Of the male population 32.9 per cent., and of the female 29.5 per cent., were under 15 years of age. The average age of males was 29.5 years and of females 31.1, as against 27.8 and 29.3 in 1911. Of male children under 15, 9.2 per cent. had lost one parent and 0.6 per cent. had lost both. The 9.2 per cent. is made up of 5.9 fatherless and 3.3 motherless. The orphanhood of female children is similar. Of males aged 15 and over, 50.6 per cent. were married and 6 per cent. widowed. Of females over 15, 45.3 per cent. were married and 10.9 per cent. widowed.

Housing.—The average number of persons per occupied house was 4.7. The number of persons per 100 (windowed) rooms was 107, the lowest on record, the figure in 1861 having been 165; in 1871, 149; in 1881, 139; in 1891, 126; in 1901, 118; and in 1911, 111. This shows a very steady and important improvement in room density, though the position differs in different areas, the statistical worst being Fraserburgh with 161 and Peterhead with 140. Of the total population (excluding the city), 1.9 per cent. live in one-roomed houses, 14.6 per cent. in two-roomed, 24.6 per cent. in three-roomed, 15.1 per cent. in four-roomed, 13.9 per cent. in five-roomed,

and 9.7 per cent. in six-roomed houses. These figures are definitely better than those of 1911.

Occupations.—Of the population 12 years old and upwards, 57.8 per cent. had remunerative occupations. The principal occupations, stated as a percentage of the total persons in occupation, were: agriculture, 34.3; personal service, 14.8; commerce (clerks excluded), 6.4; transport and communication, 6.2; wood and furniture, 4.2; making of food, drink, and tobacco, 4.1; fishermen, 4; and professional occupations, 3.8.

County of Argyll.

The population returns of the great but widely scattered West Highland county of Argyll² have been seriously affected by the postponement of the census from April 24th to June 19th, there being at the latter date considerable inflation owing to summer visitors, especially in certain localities. The total population was 76,862, or 8.4 per cent. more than in 1911. From 1801 to 1831 the population rose steadily from 81,277 to 100,973; afterwards it gradually diminished to 70,902 in 1911. The burghal population at the 1921 census was 30,111 and the landward 46,751. In the former there was an intercensal increase of 33.9 per cent., but in the latter a decrease of 3.4 per cent. There are six burghs, one of which, Dunoon, a favourite holiday resort in summer, had a June census population of 14,731, being an increase as compared with April, 1911, of no less than 114.8 per cent. The only county district with an increase is Cowal, which adjoins Dunoon. A decrease of 12.7 per cent. in Lorn district is largely explained by an inflation ten years previously of 1,009 men of the Royal Navy. Of the total county population of 76,862, the mainland parishes had 64,242 (12.6 per cent. increase), and the island parishes 12,620 (8.8 per cent. decrease). Omitting two parishes, the mainland shows a decrease from 61,130 in 1831 to 37,176 in 1921—equal to 39.2 per cent. The decrease in the island parishes since 1831 has been from 34,591 to 12,620, or 63.5 per cent.—fully one-third of a mainland loss and nearly two-thirds of an island loss. Indeed, a special recruiting ground of one of the great Highland regiments, the Argyll and Sutherland Highlanders, is sadly affected.

The area of the county is 1,990,472 acres, and the average number of persons per 100 acres is 4. In the burghal portion the average is 914, and in the landward it is 2.

Sex and Age.—The proportion of females to males is 115.5 to 100. In 1911 it was 100.1 to 100, but that census included 1,839 men of the Royal Navy. The average age is 33.6 years—males 32.8, females 31.2, being an increase compared with 1911 of 1.9 for males and 1.5 for females. Of children under 15, 12.6 per cent. had one parent dead, and 1.1 per cent. had lost both parents. Of the male population aged 15 and upwards, 45.5 per cent. were married and 5.6 per cent. widowed or divorced. The corresponding figures for the female population were 39.8 per cent. and 12.5 per cent. The divorced were 10 males and 19 females.

Housing.—The average number of persons per house is 4.59, and of persons per 100 (windowed) rooms 105—a marked improvement on previous censuses. In 1861 the proportion was 181; in 1871, 151; in 1881, 135; in 1891, 121; in 1901, 112; and in 1911, 106. In one-roomed houses there lived 3 per cent. of the population, in two-roomed 22.4 per cent., and in three-roomed 21.1 per cent.

Gaelic Speech.—Gaelic speakers are 32.7 per cent. of the county population, but all these, excepting 0.7 per cent., speak English also. Persons who speak both Gaelic and English have since 1911 diminished by 18.8 per cent. and speakers of Gaelic only by 58.4 per cent. In the islands the Gaelic-speaking population is 77.3 per cent.—a much higher rate than on the mainland, yet a decrease of 11.3 per cent. since 1911. The largest number of persons who can speak Gaelic only are younger children or old people.

Occupations.—Persons aged 12 and over having some occupation were 55.3 per cent. of the population—of males 58.7 per cent. and of females 27.6 per cent. The principal occupations, stated as a percentage of the total persons in occupations, were: agriculture, 22; personal service, 16; transport and communication, 10.2; commerce (clerks excepted), 9.4; metals, 5.7; and professions (clerks excepted), 5.2.

SCOTTISH WAR MEMORIAL.

There is a proposal, for which considerable funds have been collected, to erect a Scottish war memorial on the Castle Rock, Edinburgh. On this subject Dr. John Stevens of Edinburgh addresses us the following letter:

Sir,—With no special claim to criticize the proposed war memorial on the Castle Rock, and without imagination which soars to sky lines, the writer's only comment is that such a large demolition and reconstruction is inopportune in view of the urgent need of dwellings for the heroes. A Scottish war memorial would, however, be more in keeping with present conditions of national finance and public sentiment were it devised actively to promote the well-being and betterment of the people, not least of those who served and suffered in the war and of their dependants.

¹ Vol. I, Part 5, of Census of Scotland, 1921. H.M. Stationery Office, Imperial House, Kingsway, W.C.2. 9s. net, 9s. 2½d. post free.

² Report obtainable as for Aberdeenshire. Price 7s. net, 7s. 2½d. post free.

The purpose of this letter is to make a suggestion on these lines. It is this:

That, as a thank-offering for deliverance from grave national peril and for the maintenance of freedom, a Scottish fund be raised to place on a secure and enduring basis the provision of trained nursing for all who cannot obtain this benefit for themselves. The establishment of Queen Victoria's Jubilee Institute for Nurses has conferred inestimable blessing on the people of Scotland, but, like the voluntary hospitals, this institution labours under serious financial difficulties. The time is ripe to remedy this as well as to extend the scope of its work.

Let sufficient capital be raised to create a permanent endowment for this institution, which would enable it to provide trained nursing for Scotland adequate to the public requirements, and to continue as a voluntary agency independent of State interference or control. This would constitute a living memorial worthy of Scotland in the highest sense, and it is one which should appeal to the whole population. What investment could yield a comparable return? Such a memorial would form a fitting recognition of all—both men and women—who in any way "did their bit" in the war.

A central building would be required for administrative purposes. This would be the mural evidence of the war memorial, and would bear on its frontage a benedictive answer to the old-world question, "What mean these stones?"

The Queen Victoria Institute for Nurses (Scottish Branch), 26, Castle Terrace, Edinburgh, has for its president and honorary treasurer Princess Louise, Duchess of Argyll. It provides trained nurses for the sick poor all over Scotland. It carries on its work in entire harmony with and under the direction of Scottish medical practitioners, who, we are assured, value very highly the nursing services rendered to their patients. The scope of the work could be greatly extended if funds were available. The institute, which has recently issued an appeal for £27,000, was founded by Queen Victoria, who gave her jubilee gift from British women to improve the nursing of the sick poor. The Scottish council is composed of representatives of a very large number of public bodies, including the medical faculties of Edinburgh and Glasgow; the County and District Nursing Associations, the County Councils' Association, and several trade unions. Its affairs are managed by an executive committee of nineteen persons, of whom four are members of the medical profession; one of the honorary secretaries is Mrs. Chalmers Watson, C.B.E., M.D. All the nurses are fully trained in hospital and have received additional training by the institute to test that they are by temperament and otherwise suitable for district work, and to instruct them in medical work not usually taught in a general hospital but essential to a district nurse. There are at present 450 nurses working from the 313 branches of the institute throughout Scotland.

DR. J. R. CURRIE.

Dr. J. R. Currie, a senior medical officer of the Scottish Board of Health, has been appointed to the Chair of Preventive Medicine in Queen's University, Kingston, Ontario. After graduating M.A. Edin. (1891) he went with a scholarship to Lincoln College, Oxford, and took the B.A. there in 1896 (First Class in Classical Honour Moderations); he proceeded to M.A. in 1910. He resumed his medical education at the University of Glasgow (M.B., Ch.B. with commendation in 1898, and M.D. with high commendation in 1910). While in practice in Birmingham he took the D.P.H. of that University. His early experience of preventive medicine was gained in the sanitary department of the city of Glasgow under Dr. A. K. Chalmers, and in the counties of Stirling and Dumharton, where he acted in 1906 and 1907 as medical officer of the two counties during the absence of Dr. John C. McVail. In 1909 he was appointed medical officer of health of the city of Chester, and from 1911 to 1912 held the same office in the counties of Fife and Kipross. In 1912 he entered the service of the Scottish Insurance Commission. During the war he held for three years a commission in the R.A.M.C., and saw service in France and Italy. He acted for some months as Chief D.O.M.S. (Scotland) in the Ministry of National Service, while Dr. Norman Walker was C.M.S. On demobilization he returned to duty with the Insurance Commission, and in 1919 he passed into the service of the Scottish Board of Health. He has written a history of medical recruiting in Scotland during the war which will be published shortly.

SCOTTISH BOARD OF CONTROL.

The annual report for 1921 of the General Board of Control for Scotland, which has just been issued, states that there were in Scotland, on January 1st, 1922, exclusive of insane persons maintained at home by their guardians, 18,027 insane

persons of whom the Board had official cognizance. Of these 2,975 were maintained from private sources, 14,931 by parochial rates, and 71 from funds voted by Parliament; as compared with the previous year there was a total increase of 221. Excluding transfers, 3,855 patients were admitted to the different establishments; this was 72 more than the previous year and 418 more than the average for the years 1915 to 1919. In addition, 346 persons voluntarily entered establishments for the insane during the year; these persons were not registered as lunatics, and could not be detained for more than three days after giving notice of their desire to leave; 305 private patients (53 less than in the previous year) and 1,005 rate-aided patients (35 more than in the previous year) were discharged as recovered during 1921, and 199 private and 293 rate-aided patients were discharged unrecovered; 1,695 deaths took place during the year, the percentage being 10.1. On January 1st, 1922, there were 2,046 mental defectives on the Board's register, 462 being in certified institutions for adults, 853 in certified institutions for juveniles, and 731 boarded out in private houses.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.

At the recent examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, 133 candidates appeared. Of this number 115 were successful and 18 were rejected.

Ireland.

KILDARE COUNTY HOSPITAL.

Dr. P. J. Williams, medical officer of the Kildare County Hospital, in his report to the hospital committee stated that since his last report there had been 115 patients admitted to the County Hospital, and 88 patients were discharged after treatment. During this period seven patients died.

"On this date [Dr. Williams continues] there are 78 patients undergoing treatment. I desire to draw the attention of the Board to the fact that there is absolutely no equipment yet supplied to the County Hospital, not even that necessary for the treatment of urgent accident cases. I referred to this matter in my last report, when an order was made by the Board that the necessary equipment be supplied, but this has not yet been done. Owing to this lack of equipment I am very heavily handicapped in my work. The Board will realize the gravity of this matter when it is pointed out that during the period covered by this report, ten urgent accident cases have been admitted. In all of these cases the proper equipment for treatment was not available. In one case of a young child suffering from a complicated fracture of the femur, I was compelled, owing to the absence of the necessary appliances, to requisition the aid of the carpenter in improvising a splint. This was not a satisfactory method of dealing with the case, and is unfair both to the patient and to myself. Furthermore, in an urgent case brought here by the police, notwithstanding the fact that the patient was in a very weak condition from loss of blood, I was compelled to subject him to a further journey to Kildare Infirmary owing to the absence of instruments or appliances necessary for his treatment here. I would suggest the Board give this whole matter their very serious attention, as complete equipment for the hospital is urgently required."

The Committee made an order that the matter should be immediately forwarded to the Local Government Department with a request that it should sanction the necessary articles without further delay.

MEDICAL OFFICERS' HOLIDAYS.

Arising out of the decision of the co. Kilkenny Board of Health to reduce the remuneration of medical locumtenents a meeting of the co. Kilkenny medical practitioners was recently held, when the resolution was unanimously passed:

That we, the medical practitioners in the County Kilkenny, refuse to do ordinary vacation or sick-leave duty at a smaller fee than £6 6s. a week.

It was also agreed that the fee of £8 8s. a week be charged for temporary duty for the combined offices of Thomastown dispensary district and the county home. The following undertaking was also drawn up and has been signed by practically all doctors practising in the co. Kilkenny:

I hereby promise not to accept any appointment from any public body unless the terms of the appointment are in agreement with the opinion of the medical profession in the co. Kilkenny and not to act independently of the profession in any matter in which the interests of the profession are concerned.

APPOINTMENT OF A MEDICAL OFFICER.

We have received the following letter with reference to a paragraph published on August 26th (p. 400):

Swaulinbar, co. Cavan,

August 28th, 1922.

Sir,—I notice in your issue of August 26th (p. 400) a note re the appointment of the medical officer at Dowra Dispensary District, co. Cavan. Evidently you have not been informed by your Irish correspondent that I at once sent in my resignation to the committee when informed of the true facts of the case.—I am, etc.,
A. J. O'REILLY, L.R.C.S. and F.I.

We congratulate Dr. O'Reilly on the course she has taken. In such matters it is of the utmost importance to maintain the solidarity of the profession.

Correspondence.

THE PLACE OF VERSION IN OBSTETRICS.

Sir,—Your review (August 26th, p. 385) of Dr. Potter's monograph *The Place of Version in Obstetrics* raises a number of interesting questions. Most obstetricians will agree with you that the results quoted are excellent. But while one is compelled to accept the percentages, it does not by any means follow that the method which in his hands gives such results would give the same if universally adopted. It is not, at present, every midwifery case attended in this country which has the advantages of the surgical preparation and the aseptic precautions which are absolutely demanded by version as a routine practice, and I therefore think your criticism is very salutary.

Then, again, while there has been no maternal mortality in 938 cases, what is to be said about the morbidity? It is unthinkable that the morbidity is as low by routine version as by the usual conduct of a labour, because there must be a certain proportion of cases where in any intrauterine interference infection is carried from the vagina by a perfectly sterilized finger or hand or rubber glove. A glove is no guarantee against an infected vagina, and in ideally conducted midwifery cases, of the total number of infections, a large percentage must have their origin in the vagina and not in foreseps, etc.

It is not an easy matter to impress students with the vital importance of not attempting to extract an infant rapidly (which usually results actually in prolonged effort) when such an excellent handle for traction is apparently provided by the partially born infant's legs. I should think there is no stronger temptation to the inexperienced in the whole range of midwifery, and to perform version unnecessarily is only inviting this temptation.

Respecting the diagnosis of presentation and position, one can only say that reliance entirely on the sutures and fontanelles is surely somewhat archaic. Almost every case can, by the experienced, be diagnosed accurately by abdominal palpation, and there is no excuse for the repeated vaginal examinations in vogue some years ago. My practice is to examine abdominally about four weeks before term and again a few days before. Such examination reveals that the textbook statements of the percentage of occipito-posterior presentations is far too low; at the same time there are certainly not 60 to 70 per cent. of presentations that are occipito-posterior—at least, not in this country. Without consulting my records I would roughly estimate occipito-posterior presentations at 20 to 25 per cent. Then a further number occur where the head must fairly be described as occipito-transverse, a few of which certainly first rotate to occipito-posterior. If one could be sure that any given case would remain persistently occipito-posterior, version would be an excellent treatment, but there is no means of knowing certainly that such a case will be persistent, and by the time this is certain version is, of course, impossible. I agree that palpation of an ear, if it can be reached easily and if one must diagnose by the vagina, is an absolutely final word on the presentation.

But why internal version? If one decides to do version, external version is, in the majority of cases, quite simple. It is to be noted that when an anterior arm is brought down and the body rotated to bring the posterior arm forward, if the position up to this point has been occipito-posterior it means either that the head is rotated into the opposite posterior occipital position or that the occiput must in all cases be rotated at least a full half-circle, which latter is not always easy. If this is always possible there is no object in

performing internal version as distinct from external version in order to secure an occipito-anterior presentation of the aftercoming head.

Malposition must always be a somewhat relative term; thus, a slightly more oblique uterus than normal would give a slightly increased tendency to transverse presentation when labour began, but as a fact the majority still remain vortex presentations.

In spite, however, of these criticisms I believe, as does the writer of the review, that the interest in version will be stimulated, for it might with advantage be resorted to more often than it is.—I am, etc.,

W. OSBORNE GREENWOOD, M.D., F.R.S. Edin.

Harrogate, Aug. 28th.

CLAYDEN v. WOOD-HILL.

Sir,—Will you kindly allow me to thank the Council of the British Medical Association for the help it gave me, on the announcement of the verdict given against me in the case of Clayden v. Wood-Hill? Its offer of legal assistance and its sympathetic attitude I most deeply appreciate.

I owe a great debt of gratitude to Sir Hamilton Balfour and the signatories of the appeal fund, which raised so large a sum (£1,731) to meet the financial loss which the case entailed.

As may be realized, the sum so subscribed has been of the greatest relief to me; but, great as that relief has been, the feature that has given me the more satisfaction is that the leading men of the profession, with so vast a number of my professional brethren—men representative of all parts of the British Empire, and mostly personal strangers—should have rallied so generously to my aid. It bespeaks the view taken by our profession as to the injustice of the verdict. As an expression of good fellowship it is most remarkable. It has been to me a rainbow in a stormy sky.

The practice of our profession calls for courage and confidence; my colleagues have helped me to retain both. They may rest assured that I shall apply my powers, such as they are, conscientiously and in good faith, without regard to fortune, good or bad. "Of good fortune man should not be proud, for it is a present to him; at bad fortune he should smile, for the Fates have singled him out, to try his courage."

—I am, etc.,

Beeches, Suffolk, Sept. 2nd.

H. WOOD-HILL.

NATIONAL ASSOCIATION OF OPTICIANS.

Sir,—I read with interest Mr. Cyril Jacobs's letter in the Journal of August 19th on the National Association of Opticians, a subject of great importance to all ophthalmic surgeons.

I quite appreciate Mr. Jacobs's feelings, but now that the optician is an established entity it is too late to say, "We do not want this new class of practitioner!" What we must say is, "We do not want this class of practitioner to exceed the limits of his province!" It is quite true that the qualified opticians are actively trying to get State recognition, and I, for one, will welcome the day they obtain it, provided the craft have a definite limitation of activities—namely, sight-testing and spectacle making only.

I agree that the movements of the National Association of Opticians need to be carefully watched. It was instituted about 1910; why, I do not know. All opticians rushed to join, it without thinking, and at the present time the qualified optician is pretty well disgusted to find that the majority of the members are unqualified by examination, and that they make a prominent display of a certificate as "Member of the National Association of Opticians." This, of course, is misleading to the public. I cannot help feeling that the National Association is very misleading altogether, and if it is not I should like to see its hand exposed.

At present there are two highly estimable bodies which conduct very difficult examinations for opticians—namely, the Worshipful Company of Spectacle-makers and the British Optical Association. The papers set are a revelation in optics, and only those who go through a protracted course of study and who work hard can ever hope to pass, the result being that unqualified opticians far outnumber those who have passed one of these examinations.

Now what happens? The National Association, having in view a probable legal status for opticians, institutes a very elementary examination, compared with the Spectacle-makers' Company and the British Optical Association, and so

enables one who is unable to pass the aforesaid to style himself "qualified by examination." My own view is that this is wrong and altogether undesirable.

Between the unqualified and the qualified there is such competition that one finds innumerable examples of "not playing the game." It is astounding what one does come across in the way of patients being imposed upon.

There is only one solution to the problem, and that is to give the opticians a charter, and bind them down to observe strict etiquette, as in the case of the medical profession. This would act as does the *Dentists Register* and stop any but the qualified practising.

Opticians are now here to stay. No medical man can prevent any of his patients going to an optician to be tested for a pair of glasses, even though he advise them not to do so. It behoves the medical profession therefore to try and get a Register for Opticians, allowing them reasonable privileges. It is a duty also to the public, who are not conversant with the limitations of the optician's skill. The lay person always attributes failing sight to the want of spectacles, and not infrequently visits an optician, often to his detriment.

I have known a qualified optician sell a pair of glasses to a man with double optic atrophy, who was only able to distinguish light. I have also known a qualified optician sell glasses to a girl of 12 years who was suffering from double lamellar cataract, and whose best vision with glasses was 6/36. This girl's mother was told that it was a difficult case, and that the glasses would have to be changed frequently in order to work gradually up to the required strength of lens. Again, I have known an unqualified optician supply frequent changes of glasses to a man with simple glaucoma. This person on examination was found to be blind in the right eye, and to see only 6/36 with the left eye.

The Spectacle-makers' Company and the British Optical Association supply certificates to those who have passed their examinations on the following conditions:

1. That they refer to a medical man all cases of subnormal vision that cannot be brought up to normal with glasses; all cases of squint in school children; all cases of obvious disease.
2. That they do not canvass for spectacles.
3. That they do not use drops for purposes of refraction, except in collaboration with a medical man.

I have known every condition violated by diploma holders. I think it is high time something was done by the medical profession to get an Opticians' Register. This would mean the optician conforming to a definite code of ethics and tend to produce a better class of work; moreover, it would stop the travelling quack optician who goes up and down the country, and who is helped by many newspapers publishing astounding advertisements—a type of optician who is a menace to the public.

There is a growing tendency to teach the optician to recognize fundus disease, and with this I am in agreement, but I do want an assurance that there will be no attempt to treat disease of any kind. If an optician wishes to do more than test refraction, then it is up to him to qualify in medicine and surgery.

What is this movement that is afoot to form a kind of panel with the backing of approved Insurance Societies, in which the optician is to be paid so much for supplying glasses and so much for sight testing? Does the British Medical Association know anything about it?

Now that the matter of optician *versus* oculist has been opened up for discussion I hope it will be thoroughly thrashed out.—I am, etc.,

Middlebrough, Aug. 21st.

J. PARKINSON HIGHAM.

* The movement referred to in the penultimate paragraph is within the cognizance of the Insurance Acts Committee, and is being carefully watched and dealt with as far as possible.

STERILIZATION OF MENTAL DEFECTIVES.

SIR,—In the interesting letter of Sir G. Archdall Reid in your issue of August 26th he says that if he is correct in his reasoning, a single idiot may taint the whole race. That is exactly my contention; therefore the sterilization of mental defectives, although excellent, is not enough. We ought to prevent their advent in the future by sterilizing those who are certain, from pronounced family history, to produce idiots. The strongest argument in favour of my suggestion is heredity. Nageli calls the hereditary substance represented by the sexual pro-nuclei which fuse together in the act of fertilization by the name of "idioplasm." The resulting germ contains the images of two individuals, and is therefore

capable of transmitting by heredity their characters to the individual developed from it. Professor Luciani says that we are forced to admit the hypothesis that the development of the germ does not consist in a new form, or epigenesis, but rather in the transformation of a model or rough sketch into a complete organism, capable, in its turn, of forming a model similar to that from which it was itself derived.

My suggestion means a State certificate of marriage, and the power of withholding it in the case of either the male or the female who refuses sterilization, which would in no way interfere with married life. At the present moment there are over 12,000 registered mental defectives for whom we are taxed. The logical conclusion is that the effect of a State certificate of marriage would be a healthy race, with no necessity for sterilization. But although the majority may agree to this State certificate, it will take a long time to make it law, for the general public, in spite of the natural desire to have healthy children, are indifferent.

I must not further trespass on your space, but may refer anyone interested in the subject to the paper on "Sterility with reference to the State" recently brought by me before the Obstetrical Section of the Royal Society of Medicine, and published in your issue of March 18th (p. 427); the discussion which followed was reported in the same number (p. 438).—I am, etc.,

London, S.W., Aug. 28th.

R. A. GIBBONS.

SIR,—In his interesting and instructive letter published in your issue of August 26th Sir Archdall Reid tells us that the statement that acquired characters are (or are not) inherited depends on a misuse of terms. He further declares that the reproduction (not inheritance) of abnormalities (for example, idiocy) is alternate. As this statement is directly contrary to Mendelian teaching, and as Sir Archdall Reid's views on this important subject appear to be entirely unorthodox, it would be interesting if he would tell us why he thinks that the statement that acquired characters are (or are not) inherited depends on a misuse of terms. His reasons for disagreeing with the Mendelians are not apparent.—I am, etc.,

Portsmouth, Aug. 28th.

W. BASTIAN,
Surgeon Commander R.N.

SIR,—It would indeed be surprising if it were possible to find a flaw of fact or reasoning in a letter by so erudite a scholar as Sir Archdall Reid on a subject in which he is *facile princeps*. It is only in the last line of his letter that difference of opinion can occur—namely, that the necessary conclusion is sterilization.

Segregation has not so far been properly tried in the case of mental defect, and, although expensive, if our data are correct it should be a steadily diminishing expense, and should be, as it has been put, "a good long-term investment." Taking legislation, of a sterilization type, as against mental defect, I would fear the results to the community of the former more than the latter.—I am, etc.,

Melton, Suffolk, Aug. 28th.

JAMES R. WHITWELL.

THE ECONOMICS OF PUBLIC HEALTH.

SIR,—In the discussion (p. 341) on Colonel Fremantle's admirable paper the report might suggest that I said that "too much was being spent on public health services." Such was not the meaning intended at all events. Glasgow was only intended as an illustration, but now we know (see *JOURNAL* for August 26th, p. 399) that out of a population of over a million over 600,000 persons live in one-roomed or two-roomed tenements. Such a state of affairs passes the comprehension of the most imaginative, but no wonder that Glasgow is a centre of unrest. It all emphasizes the point, however, that large sums of money will have to be spent to remedy these ills, and that from the statesman's point of view economy in spending the money will only be achieved by getting the utmost value for the money spent. This may mean bold and imaginative action; but who can doubt that such action, which would give a large measure of health to all, will really result in immediate economy to the State in lives saved, and a higher quality of life for thousands?—I am, etc.,

Letchworth, Aug. 27th.

NORMAN MACFADYEN.

BOTULISM.

SIR,—With regard to the eye symptoms in botulism, I would like to mention the following case:

At midnight on August 28th I was called to see Mrs. C., aged 32. About 6 p.m. she had eaten a portion of corned beef from a three-quarter pound tin, and with it some,

tomatoes. About 7 p.m. she had a feeling as if she had been hit on the right side of her head. When she went up to bed at 8 p.m., she fell full length on the bedroom floor. At 10 p.m. she vomited the beef and tomatoes. When I saw her she was hot and flushed; could not raise her head without feeling everything in the room going round. She complained of diplopia. There was very marked nystagmus. She was retching from 2 p.m. till 1.30 p.m. next day. She did not sleep for two nights. There was no diarrhoea. The nystagmus lasted till Thursday, August 10th, and the diplopia till Saturday. On Sunday she could read steadily. On August 26th there was still some pain on the right side of the head, but otherwise she was quite well. I have never seen before such a combination of symptoms. Two children partook of small portions of the same food, but suffered no ill effects.—I am, etc.,

Helston, Cornwall, Aug. 28th.

FERDINAND REES, M.D.

SOME CAUSES OF LONGEVITY.

Sir,—It is important that scientists should not be led astray by the popular ideas of the passing day.

In this decade, when men's minds tend to become obsessed with the potency of suitable injections and inoculations, it is well to recall the important problems of dietary in their relation to longevity.

Dr. Smith, the first graduate of the American College of Physicians, who has just died as a centenarian, laid down as his first maxim of extended life and health, "Eat hardly any meat," and as his second, "Drink lots of milk."

My experience in dietetics would lead me to modify and add to these maxims as follows: (1) Eat no flesh food. (2) Drink fresh milk or naturally soured milk, but avoid all milk which is prevented from souring by antiseptic preservatives or by boiling. (3) Use oils freely. (4) Make use of days of abstinence and periods of fasting.

These are modifications of old sanitary laws of dieting evolved by age-long experience and are based upon the principle that the commoner causes of illness and early decease result from the presence of pathogenic organisms in the intestines, whence they become ambulatory and invade other organs, and that an alimentary canal should permanently contain only those organisms that are beneficial to the functions of digestion.—I am, etc.,

London, W., Aug. 30th.

JOSIAH OLDFIELD.

Obituary.

We regret to record the sudden death on August 17th of Dr. W. P. WARREN of Enfield from cerebral apoplexy. He was born at Cork in 1860, and studied first at Queen's College and subsequently at Edinburgh and St. Bartholomew's Hospital. He took the diplomas of L.R.C.P., L.R.C.S. and L.M.Edin. in 1882, and the D.P.H. in 1908. He settled in practice at Enfield Highway in 1888, and lived and worked there for thirty-four years. In the course of some years he became the senior partner in a firm of four men who had in their hands the whole medical practice of the huge and now thickly populated district between Waltham and Tottenham. In 1908 he was appointed medical officer of health for Enfield, a post in which he was eminently successful and did most valuable work in the district which came under his care. His personal popularity with his colleagues made them all most eager to help him. He paid special attention to the spread of epidemics, and had a keen gift of tracking down and isolating carrier cases which were helping to spread disease. By his efforts infantile mortality decreased considerably in the district and the general death rate as well; for some years Enfield had the distinction of smaller infantile and general death rates than any other place in London or England and Wales. His wise advice and experience were often sought by his colleagues in cases of outbreaks of infections and were readily and cheerfully given; it is doubtful if there was a medical officer of health in any town or district who was a more general favourite amongst his colleagues. Personally they will all miss him very much; he was *persona grata* at all medical meetings and dinners in the neighbourhood. He filled many posts, such as police surgeon, surgeon to many Oddfellows' and Foresters' lodges, parish medical officer and vaccinator, and was a very eminent member of the Masonic Order. He leaves two sons who worked with him of late years in his practice.

We regret to record the death of Dr. CLEMENT JOHN BAKER, which took place on August 7th at sea while he was on his way home from Uganda. He had almost completed twenty years in the Uganda Medical Service. He was born at Yoxall Rectory, Staffs, in 1872, and was educated at Bury St. Edmunds Grammar School and Middlesex Hospital. He took the diplomas of M.R.C.S.Eng., L.R.C.P.Lond. in 1893; he was house-surgeon at Middlesex Hospital, and after two years in private practice went to the Boer war as civil surgeon (1901-2). While medical officer at Entebbe he found a trypanosome in the blood of a prisoner, and was the first to announce publicly the discovery of trypanosomes in human beings in Uganda. Dr. Baker was appointed the first chief sanitary officer for the Uganda Protectorate, and held this post at the time of his untimely death. He was a most popular officer, and will be much missed among all classes of the community of Uganda. He leaves a widow, and we extend our sympathy to her, and also to his mother and other relatives.

NINIAN ALEXANDER WILLIAMSON, M.D., late Assistant Surgeon A.M.D., died at Carzield, Kirkcaldie, Dumfriesshire, on August 12th, aged 80. He was born on November 16th, 1841, and entered the army as assistant surgeon on March 31st, 1868, serving for eight years in the 7th Dragoon Guards, or Black Horse, but resigned his commission early in 1877, since when he had resided on his property at Carzield. He took an active part in public affairs, and was, or had been, a member of the Dumfries County Council, of the Kirkcaldie Parish Council, of the Kirkcaldie School Board, and a director of the Crichton Royal Institution, Dumfries. His wife predeceased him some eighteen months ago.

The Services.

AUXILIARY R.A.M.C. FUNDS.

At the last quarterly committee meeting of the Auxiliary Royal Army Medical Corps Funds grants were made to ease in the Benevolent Branch for the orphans of officers amounting to £500, and grants in the Relief Branch for the widows and children of rank and file amounting to £317. These funds are for the relief of widows and orphans of commissioned officers and non-commissioned officers and men of the rank and file of the Royal Army Medical Corps, Special Reserve, Territorial Force, and New Armies, and also for the relief of the children of those who have been so severely disabled in the late war that they need help for the education of children. Requests for relief should be addressed to the Honorary Secretary at the offices of the Funds at 11, Chandos Street, Cavendish Square, W.1.

LECTURES ON DENTAL HYGIENE.

THE Admiralty, with the view of encouraging proper care of the teeth and to maintain a high standard of dental health, has given orders that dental officers are to supplement, by a series of lectures on oral hygiene, the individual instruction given to patients.

Suitable lantern slides for lectures will be supplied by the Lecture Department at the Royal Naval School of Dental Hygiene, if necessary, he will be given monthly at the training establishments and depôts, or as frequently as the commanding officer may consider desirable. All new entries must attend as part of their general instruction; the attendance of other ratings is voluntary.

DEATHS IN THE SERVICES.

Deputy Surgeon General William Howland Roberts, Madras Medical Service (retired), died at Chelsea on August 16th, aged 87. He was born on September 29th, 1834, and educated at Edinburgh, where he graduated as M.D. in 1855. Entering the I.M.S. as assistant surgeon on July 23rd, 1858, he became D.S.G. on July 1st, 1888, retiring on July 1st, 1893. He served in the Burma war in 1886-87, was mentioned in dispatches in G.G.O. No. 474 of 1887, and received the medal.

Colonel James Francis Supple, C.B., R.A.M.C.(ret.), died suddenly at Haywards Heath railway station on August 8th, aged 78. He was born at Waterford on December 14th, 1843, and educated in Dublin, and after taking the L.R.C.S.I. in 1855 and the L.R.Q.C.P. in 1856, entered the army as assistant surgeon on April 1st, 1857. In the regimental days he served in the 1st Foot, the Royal Regiment, or Royal Scots. After thirty years' service he attained the rank of colonel on May 29th, 1898, and was granted the local rank of surgeon general while serving as P.M.O. at the base in Cape Town in the South African war, on November 18th, 1899, retiring on December 14th, 1903. He served under Sir Garnet Wolseley in the Ashanti campaign of 1873-74, in the defence of Foomanah, medal with clasp; in the Afghan war of 1878-80, medal; in the Burma campaign in 1886-87, as senior medical officer of the 6th Brigade, mentioned in dispatches, *London Gazette*, September 2nd, 1887, medal; and in the South African war in 1899-1900, as P.M.O. at the base, mentioned in dispatches, *London Gazette*, April 18th, 1901, Queen's medal with clasp, and C.B.

Lieut.-Colonel Algernon Francis Stevens, Bengal Medical Service, died of cholera at Gaya on August 20th, aged 51. He was born at Arrah in Behar, on August 30th, 1869, the son of the District magistrate, Mr. C. C. Stevens, afterwards Sir Charles of Bengal. He was educated L.R.C.P. Lond. in 1893, after which he entered the I.M.S. as assistant-lieutenant on January 29th, 1895, attaining the rank of lieutenant-colonel after twenty years' service. His first five years were spent on military duty. In 1900 he entered civil employ under the Bihar, and served as civil surgeon of Hugli, Ranchi, and others. In 1911 he returned to military duty, at which he remained for the rest of the war, and up till December, 1920, when he returned to civil work. He served in medical charge of the hospital ship *Erimvura* from June, 1916, to December, 1918. His elder brother, Lieut.-Colonel C. R. Stevens, also of the Bengal Medical Service, after also serving in the late war, died on November 18th, 1919.

Lieutenant-Colonel Donald Eleum, Madras Medical Service (retired), died in a nursing home in London on August 11th, aged 69. He was born on May 28th, 1853, the son of Dr. Charles Frederick Eleum, of Cheltenham, educated at Cheltenham College and at Guy's, and after taking the L.S.A. in 1875 and the M.R.C.S. in 1876, entered the I.M.S. as surgeon on March 31st, 1877. He retired as surgeon-major on March 10th, 1895, but was promoted to lieutenant-colonel from October 18th, 1902, for services in England in connection with the South African war. He served in the Afghan war of 1878-80, medal; in the Burma war in 1885-87, mentioned in dispatches, G.G.O. No. 434 of 1887, medal; and in the war of 1914-19, mentioned in dispatches in *London Gazette* of January 22nd, 1919, and June 5th, 1919. For some years past he had held the appointments of examiner of surgical instruments and extra member of the Invaliding Board of the India Office.

Major Patrick Sampson, D.S.O., R.A.M.C., died at Cricklade on August 30th, aged 41. He was born on January 4th, 1881, the son of M. Sampson, Esq., of Knocklong, Limerick, and educated at Queen's College, Cork, taking the double qualification of the Irish Colleges in 1903, and subsequently their D.P.H. in 1913. Entering the R.A.M.C. as lieutenant on January 30th, 1906, he became captain after three and half years, and major after twelve years' service. He served in the war of 1914-18, was thrice mentioned in dispatches, in the *London Gazette* of December 1st, 1914, February 17th, 1915, and January 1st, 1916, was wounded, and received the D.S.O. on December 1st, 1914.

Captain Charles Leslie Grovo Powell, M.C., R.A.M.C., died of heartstroke at Milton on July 18th, aged 30. He was born on February 17th, 1892, and educated at St. Thomas's. He took the M.R.C.S. and L.R.C.P. Lond. in 1915, and immediately entered the R.A.M.C. as a temporary lieutenant on May 7th, 1915, becoming captain after a year's service, and received a permanent commission, ranking as captain from November 7th, 1918. He served in the recent war, was mentioned in dispatches in the *London Gazette* of June 15th, 1916, and received the Military Cross on November 17th, 1917.

Medical News.

DR. F. J. WALDO has received many congratulations on the completion of twenty-one years' service as coroner of the City of London and Southwark. Dr. Waldo, who is a barrister as well as a medical man, was the first medical officer to the Inner and Middle Temples. At its last meeting the Court of Common Council, in order to mark its appreciation of his services, voted Dr. Waldo an annual increase in his remuneration of £150.

At the opening of the winter session of the Middlesex Hospital on Tuesday, October 3rd, at 3 p.m., the introductory address will be given by Professor Sidney Russ, D.Sc. (Joel Professor of Physics), after which the prizes will be distributed by H.R.H. Princess Alice, Countess of Athlone. The annual dinner will be held at the Trocadero at 7.30 p.m. on the same day. Mr. Sampson Handley, M.S., will preside. Those wishing to be present at the dinner should communicate with the Secretary-Superintendent of the hospital.

The annual dinner of the past and present students of Westminster Hospital will be held at the Wharfedale Rooms, Hotel Great Central, on Monday, October 2nd. Mr. Arthur Evans, M.S., F.R.C.S., will take the chair at 7.30 p.m. The secretary is Dr. Adolphe Abrahams, 17, Harley Street, W.

A POST-GRADUATE course in medicine, surgery, and pathology will be held at the Radcliffe Infirmary, Oxford, from October 2nd to October 7th. The course will comprise morning sessions from 10.30 a.m. to 1.30 p.m., and afternoon sessions at 2.30 p.m. and 4.30 p.m. Tea will be provided in the library each afternoon at 4 p.m. A dinner will be held in Queen's College Hall at 7.30 p.m. on October 7th. A limited number of those attending the course may be accommodated in rooms at Queen's College, for which early application should be made to the Bursar, Queen's College. The fee for the course is 1 guinea for practitioners in the hospital area and 2 guineas for new members from elsewhere. Further information may be obtained from the secretaries of the post-graduate course, Radcliffe Infirmary, Oxford.

THE annual dinner of the past and present students of St. Mary's Hospital Medical School will be held at the Connaught Rooms, Great Queen Street, W.C., on Monday, October 2nd, at 7 for 7.30 p.m. The chair will be taken by Sir Leonard Rogers, C.I.E., F.R.S. The secretary is Dr. A. Hope Gosse, 15, Queen Anne Street, W.1.

THE programme of the North-East London Clinical Society for the session 1922-23 has been issued. The opening meeting is arranged for Thursday, October 5th, at 4.15 p.m., when a lantern lecture will be given by Sir Archibald Reid on "The x-ray examination of the pyloric end of the stomach and its vicinity." The annual dinner will be held on October 12th, at 8 for 8.15 p.m., at the Prince of Wales Hospital, Tottenham. Subsequent clinical meetings will be held at the beginning of each month from November to June inclusive.

DR. HARVEY CUSHING has been awarded the Charles Mickle Fellowship of the faculty of medicine of Toronto University. He has stipulated, however, that the money, which amounts to 1,000 dollars, shall be used to send a graduate of Toronto University to Harvard to work with him. The Charles Mickle Fellowship, endowed by the late Dr. W. J. Mickle, is awarded annually to the member of the medical profession anywhere who is considered to have done most during the preceding ten years to advance sound knowledge of a practical kind in medicine. The first award was made last year to Professor Pavlov of Petrograd.

THE following courses of lectures and demonstrations will be given during the coming autumn term at the Royal Sanitary Institute: a course for sanitary officers, commencing on September 27th; a course for meat and food inspectors, commencing on October 6th; and a course for women health visitors and child welfare workers, commencing on September 29th. Dr. Louis C. Parkes will give an introductory lecture to the students in the several courses on September 25th at 5.30 p.m. Further information can be obtained from the Secretary of the Institute at 90, Buckingham Palace Road, S.W.1.

THE Post Office has issued a circular stating that it is endeavouring to make up leeway, and is, in particular, actively engaged in developing telephonic facilities in rural districts. It is estimated that out of 3,110 existing exchanges 1,930 serve purely rural districts. In addition the service has been extended in the form of a public call office to 2,250 villages where no exchange exists. Attention is being given to the extension of automatic telephony. Automatic exchanges are already working in sixteen places. The largest automatic exchanges are at Leeds, with 9,600 lines, and Portsmouth, with 5,000 lines. Works are now in hand for converting to the automatic principle the exchange systems at Sheffield, Dundee and Broughty Ferry, Gloucester, Gosport and Brockhurst, Kirkcaldy and Dysart, Shrewsbury, Southampton, Swansea, Torquay, and York, while over thirty other schemes are being developed. The sum of £2,230,000 is being spent this year on the development of the trunk wire system.

THE "European Student Relief" of the "World's Student Christian Federation" has appointed a committee to co-operate with the "Universities' Library for Central Europe," co-ordinating the work of securing by gifts, exchange, and purchase, British books, journals, etc., for students, professors, and libraries in the universities of Central Europe. Donations of books, periodicals, and money will be gratefully received by Mr. B. M. Headcar, Universities' Library and Student Relief for Europe, London School of Economics, Houghton Street, London, W.C.2.

H.M. STATIONERY OFFICE has printed a Consolidated List of Parliamentary and Stationery Office Publications issued from January 1st to May 31st, 1922. In it the net price and the price with postage are both given. Publications issued by the Stationery Office can be obtained through any bookseller, but a bookseller is not always disposed to obtain a copy of one of the shorter papers published at the price of a few pence; it may often be convenient to obtain such a paper by writing to the Stationery Office. Its addresses are Imperial House, Kingsway, London, W.C.2, and 28, Abingdon Street, London, S.W.1; 37, Port Street, Manchester; 1, St. Andrew's Crescent, Cardiff; and 23, Forth Street, Edinburgh.

THE 50th anniversary of the Society of Serbian Medical Practitioners will be celebrated at the University of Belgrade on September 21st. On the morning of that day there will be a solemn commemoration of medical men who died in the discharge of their duty during the war, followed by an address by the vice-president and an historical statement of the development of the society by the secretary. Afterwards addresses will be delivered by delegates. In the afternoon visits will be paid to various public health institutions in Belgrade, and in the evening a banquet will be held.

PROFESSOR WEIL, who gave his name to the Weil-Felix reaction, has recently died from typhus, which he contracted during his experiments on the disease.

LECTURES on "Health of the Mind and Body—How to Obtain and Preserve it," are being delivered by members of the Medical Council of the People's League of Health at Wormwood Scrubs, Wandsworth, Pentonville, and Holloway Prisons, London. The work has the sanction of the Home Office, and will be extended during the coming autumn and winter to all prisons throughout the country.

THE new Darling Building in the Medical School of Adelaide University, South Australia, was opened recently by Sir George Murray. It is to be devoted to the departments of the fundamental sciences in the faculty of medicine, as there has been inadequate accommodation for the teaching of anatomy, physiology, and pathology. The family of the late Mr. John Darling contributed £15,000 towards the erection of the building. In declaring it open Sir George Murray gave an account of the development of the medical school from the establishment of a lectureship in physiology down to the present extension of the school. The library of the Darling Building will accommodate the library of the South Australian Branch of the British Medical Association, as well as the medical library of the university.

THE courses in the Harvard School of Tropical Medicine, Boston, U.S.A., will begin on September 25th and continue until June 1st, 1923. The courses are open to graduates from recognized medical schools. Properly qualified students (not necessarily graduates of medicine) are admitted to single courses or to any number of courses which they may select from the various subjects offered. The school aims at giving an adequate preparation to those who intend to practise medicine where tropical or exotic diseases may be prevalent or occasionally encountered, to pursue original investigations in relation to exotic disease, and to organize prophylactic measures against infectious diseases. Candidates who are graduates of medical schools of recognized standing, and who have completed the full course in tropical medicine, have passed the required examinations, and have also complied with all other requirements, will be given a diploma in tropical medicine. Applications for admission to the school should be made to the director.

THE first annual balance-sheet of the Barking Hospitals' Welfare Fund shows the excellent results that may be attained by a well-organized system of collecting a penny a week from house to house in aid of the voluntary hospitals. Barking has some 31,000 inhabitants, mainly of the working classes, and its Welfare Fund amounts to over £1,283; of this, £403 has been allocated to the London Hospital, £275 to Poplar Hospital, £100 to St. Bartholomew's, and the balance to eleven other hospitals in varying proportions.

THE Government of Czecho-Slovakia has decided that patients proceeding to Pistan shall, on production of a doctor's certificate, pay half the usual fee for a passport visa.

THE Star and Garter Home for Disabled Sailors and Soldiers, which was established by the British Red Cross Society, and has hitherto been managed by a committee of that society, has recently been constituted an independent charity under a scheme prepared by the Charity Commissioners on the application of the society. It will be administered by a body of governors comprising the former members of the Star and Garter Committee, with the Hon. Sir Arthur Stanley as chairman and Sir William H. Bennett as vice-chairman. The appointment of additional governors is vested in the British Red Cross Society. Field-Marshal Lord Grenfell, Lord Leverhulme, the Mayors of Richmond (Surrey) and Folkestone, and the Chairman of the Sandgate Urban District Council have consented to become vice-presidents.

IT is announced that Engineer Vice-Admiral Sir George Goodwin, K.C.B., late Engineer-in-Chief of the Fleet, and Dr. James Colquhoun Irvine, C.B.E., F.R.S., Principal of St. Andrews University (formerly Professor of Chemistry, Glasgow), have been appointed members of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research.

THE *Sphinx* has published a special tourist number, entitled *Egypt*, in anticipation of the Cairo season of 1922-23. Among the articles it contains is one recommending the country as the world's winter playground. Dr. Gerald Garry contributes another on Egypt as a health resort, and this, as well as other articles on various aspects of life in Egypt and the Sudan, are copiously illustrated. Copies can be obtained on application to the Secretary of the Egypt Promotion Association, Post Box 930, Cairo, or to tourist agencies in this country.

THE Board of Trade has received a notice of complaint that "acid acetic 80 per cent. grade or higher" has been improperly excluded from the lists of articles chargeable with duty under Part I of the Safeguarding of Industries Act. Any person directly interested should communicate with the Assistant Secretary, Board of Trade (Industries and Manufactures Department), Great George Street, London, S.W.1.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notices to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology*, Westrand, London; telephone 2630, Gerrard.

2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 15, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

"ALPHA" asks if it would be beneficial and safe for a child of 4 years to sleep in an open-air shelter, about 1,000 feet above sea level, in a Derbyshire district. The atmosphere is at times very foggy and cold during autumn and winter. The child is suffering from tuberculous glands, which have been twice operated upon, and has benefited by open-air treatment in the daytime during the summer.

DR. J. R. BARRISKILL (Sydney) writes, in reply to "Baffled" (April 15th, p. 629), to suggest that if the patient gives up smoking and takes a small dose of a saline laxative in half-a-tumbler of cold water the foul breath will cease to trouble him.

TREATMENT OF GALACTORRHOEA.

"X." asks for advice as to the treatment of galactorrhoea in a woman aged 24, with one child born twelve months ago. Belladonna, purgation, and dry diet, as well as hindering the breasts tightly, have been tried with no marked effect. The quantity of milk varies from 2 to 4 pints a day, sometimes more. Treatment reduces the quantity to half only.

INQUESTS IN WORKHOUSES IN IRELAND.

"R. G. M." asks if a medical officer in charge of a hospital who is notified by the coroner to give medical evidence as to the cause of death at an inquest (in the case of a man killed in an accident and brought dead to the hospital) is entitled to a fee.

"*." We are informed that the medical officer of a workhouse hospital in Ireland is not entitled to a fee for inquests held on bodies placed in any part of the workhouse buildings—even when the dead body is brought in from outside for convenience in holding the inquest.

WARTS OF THE SCALP.

DR. JOHN A. FRANCIS (London) writes to suggest that "X. Y. Z." (August 5th, p. 240) might try the following mixture:

R. Magnes. carb. lev.	5ij
Pulv. tragac. co.	5ss
Aq. chlor.	ad 5viij

3j three times a day.

He says that in one case of a man with an uncountable number of warts on the scalp, and in a case of a young woman with the same condition on the face, the warts all disappeared in a few days. The treatment does not seem to have any effect on the ordinary warts on the hand.

INCOME TAX.

"R. W. S." is a partner in a practice in connexion with which a house is occupied of which five rooms are used for the practice and only two bedrooms, the kitchen, and part of one of the five "professional" rooms are used for private purposes. He asks whether he can claim two-thirds of the rent, rates, etc.

"*." Yes; two-thirds would seem to be a reasonable proportion in the circumstances. The authorities usually refuse any additional claim based on the ground that the house is more expensive than would normally be required, and there is no clear justification for including any special charge on that account. "R. W. S." might, however, put forward the argument that the cost of the professional portion is not less than three-quarters of the total amount paid. In such a claim as this everything turns on the actual circumstances of each case.

D. P." holds an appointment in Government service abroad. e proposes to spend eight months in this country from March 1st, 1923. What income-tax will he be liable for in this country?

* It is assumed that "L. D. P." does not maintain a residence in this country during his absence abroad, and that the present rates of tax will remain in force for 1922-23. The tax payable could be as follows:

Amount of pay in United Kingdom between April 5th, 1923, and date of departure (say)	£700
Deduct—	
...	£270
...	£225
...	£36
...	£12 10 0
...	£343 10 0
Of which £225 at 2s. 6d. in £ =	£23 2 6
And balance £131 10s. at 5s. in £ =	£32 17 6
	£61 0 0

"N. R." bought a secondhand car in 1921 for £140, and sold it in July, 1922, for £90, buying a new light car for £275.

* The allowable expense is £140-£90—that is, £50; the additional expenditure actually incurred represents capital outlay in improving the equipment of the practice. It should be understood that the expense is taken into account in computing the year's profits, and not deductible in one sum from the average profits of the previous three years.

LETTERS, NOTES, ETC.

ESTIMATION OF THE TOXICITY OF ORGANIC ARSENIC COMPOUNDS.

A. W. R. G. ATKINS (Marine Biological Laboratory, Plymouth) writes with reference to the difference in toxicity of different batches of the same organic compound of arsenic, which has made it necessary to test the toxicity of each fresh sample by injections, to suggest that since the compounds in question are hydrochlorides of weak bases or sodium salts of weak acids, it may be possible to differentiate between pure preparations and those either originally impure or which have become so through oxidation, by determining the hydrogen ion concentrations colorimetrically. These determinations may be made with rapidity by adding a few drops of a suitable indicator. The results might be correlated with those afforded by the more tedious and costly toxicity tests. The hydrochlorides are easily neutralized with sodium bicarbonate before injection, but it may be remarked that if subsequently sterilized by boiling, the loss of carbonic acid may result in producing a reaction considerably more alkaline than that of the body (about pH 7.4). In this connexion the results of Williams and Swett (Proc. Soc. Expt. Biol. and Med., 1922, 19, No. 6, 266-263) are of interest. These workers found that several preparations of salvarsan when prepared according to the directions of the manufacturers, ranged from pH 11.53 to 11.99. Silver-salvarsan, pH 10.71; neo-salvarsan, pH 8.55 to 9.22. Solutions of glucose were found to be markedly acid, being under pH 5, and normal saline varied from pH 6.4 to 4.95, and it is recommended that they should be brought more nearly to the reaction of the blood by adding mono- and di-potassium phosphates. Williams and Swett state their belief that the difference in the pH value of the injection and the blood is the main cause of sore arms following subcutaneous injections.

BATHROOM DANGERS.

Dr. A. LAPHORN SMITH writes: In the aggregate many valuable lives have been lost by accidents similar to that which caused the death of the late Sir Arthur Pearson. A leading lay journal has asked whether the medical profession cannot offer some suggestion by which this accident might be prevented. What probably happens in most, if not all, the cases is as follows: The bath is filled with very hot water and the person steps into it, not counting that the bottom is concave and very slippery, so that as soon as his full weight rests on the bottom of the bath it slips from under him and he falls, striking the head on the taps at one end, or on the solid rim of the bath at the other. This stuns him for a few seconds, during which he slides down in the bath and is completely covered, and while in this helpless condition is quickly drowned. Many bathrooms are fitted with an electric bell on purpose to call for help, but naturally this is of no use in such a case. The accident can, however, be prevented by a simple and inexpensive appliance which I have fitted to my own bath—namely, a strong steel hook screwed firmly into a beam in the ceiling immediately over the centre of the bath, from which is suspended a strong piece of

... in the hand, so the quite independent... would certainly render impossible such as caused the death of Sir Arthur Pearson known and useful people. Another cause

of danger to which I think the profession should call the attention of patients is the extremely high temperature at which they, especially women, have accustomed themselves to take their bath. This high temperature draws an enormous amount of blood away from the head and towards the skin. This may result in a fainting spell, and as the water is oftentimes much deeper than is necessary the person is easily drowned.

"THE COLD-WATER DOCTOR."

Dr. C. JOYCE (Pinjarra, W. Australia) writes: I was delighted to see the letter by Dr. Thos. Carruthers in your issue of May 13th, p. 786, and to know that others have seen the folly of attempting to administer nourishment which is not assimilated in acute febrile disease. About twenty years ago I began withholding all food in the acute gastro-enteritis of infants. The wonderful success of the plan led me to stop food in any other condition where the digestive function is in complete abeyance. I have been in charge of the Government hospital of seven beds at Pinjarra for nine years. During that time all cases of acute febrile disease have been allowed no food but lemon and orange juice, and are encouraged to drink plentifully of cold water until the appetite returns to normal temperature. I return to a normal temperature to the results in antitoxin: having unfortunately had considerable experience of diphtheria before that happy day, I realize the magnitude of the statement. Until 1918 I had not the opportunity to try the plan, extensively in influenza, but I had the unique experience of finding every patient make a complete recovery in that epidemic. I had taken the precaution of warning the public through the medium of the local paper, advising everyone who felt ill to drink water only plus a good dose of Epsom salts; consequently all my patients had water only from the inception of the disease. I fully appreciate Dr. Carruthers's remarks about the difficulty of getting the profession to break away from textbook tradition.

CONTINUOUS OXYGEN APPARATUS.

Dr. FREDERIC VICARS (Wimbledon) writes: The apparatus described by Dr. Geoffrey Bourne in your issue of July 8th (p. 40) is only an elaboration of a simpler one invented some years ago by my friend the late Dr. George Stoker. This consists of a rubber bag with a capacity of one cubic foot. Attached to it is a rubber tube, and at the further end of the tube is an ordinary rubber tent. The bag is filled with equal parts of oxygen and air, and introduced by an one nostril and fitted into the ears and held behind the head. The other nostril is plugged with cotton-wool. The bag of diluted oxygen (50 per cent.) gradually collapses under the pressure of a light weight placed upon it. When empty it is refilled as often as necessary. The apparatus is very simple and the results attending its use are very satisfactory. It can be obtained from the original maker—Fellows, chemist, Hertford Street, Mayfair.

RADIOTHERAPY.

Mr. H. FLECKER, F.R.C.S. (Melbourne), writes to express his disagreement with a statement in a paragraph published in the BRITISH MEDICAL JOURNAL of May 13th, 1922, p. 776. It gave the substance of a notice with regard to the early treatment of cancer, issued by Dr. C. K. Millam, M.O.H. Leicester. It was said that treatment by radium or x rays, though hopeful, is still in the experimental stage, and that "although many alleged 'cures' have been announced, there are none which have so far been proved to be permanent." Mr. Flecker is of the opinion that "who has had actual experience of, or who has done the work done by various radiologists using currents of about 200,000 volts, will fail to admit a vast improvement in the results as compared with older methods."

A CLASS-CONSCIOUS CONSCIENCE.

A CORRESPONDENT tells us that a conscientious objector submitted the following grounds for obtaining exemption of his child from vaccination in a district not far distant from London: "Vaccination is a trick of the capitalist to get the workers' children inoculated so that their brain will not develop so that they will remain serfs."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 34, 35, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 32, 33, and 34.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 108.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
...	0 1 6
...	7 10 0
...	3 15 0
Half page...	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so designated.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive poste restante letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

162. Gonorrhoeal Endocarditis.

G. LION and M. LÉVY-BRUHL (*Arch. Mal. du Cœur, des Vaisseaux et du Sang*, May, 1922, p. 289) give brief notes of five fatal cases of gonorrhoeal endocarditis recorded by French and American authors, four patients being young men and one a little girl aged nearly 2 years. In addition to these, 58 cases have been collected by Sagot, who found endocarditis only on the left side of the heart in 48 cases. The aortic orifice only was attacked in 27 instances, both aortic and mitral lesions were found in 8 cases, while in 13 others the mitral valve only was affected. In 6 cases lesions were on the right side of the heart, while in 4 others both sides of the heart were affected. Only 26 per cent. of the patients were females. They now record the case of a woman, aged 29, who had a healthy child aged 8, and no subsequent pregnancy. She was admitted to hospital on October 29th, 1920, having been confined to bed since the onset of generalized rheumatism two months previously. After treatment by sodium salicylate, swelling and pain disappeared from all joints except the left shoulder. Fever, however, persisted, the temperature rising every evening, with shivering followed by profuse sweats. She was emaciated, weak, and anæmic, with a generalized chronic dermatitis, especially over the knees, and scanty mucous sputum with a few scattered bronchitic râles heard at the back. The patient complained of occasional palpitation, the heart was dilated, the apex-beat being in the fifth interspace outside the nipple line. Pulse 95, regular. In the "aortic" region a soft blowing diastolic bruit with maximum intensity at the base of the xiphoid was heard; here there was also a faint systolic bruit, and a hæmic murmur over the jugulars. Nothing abnormal was found in the abdomen except that the spleen was just palpable. She had no appetite and took no food but a little milk. The stools and urine were normal. The symptoms persisted, vomiting commenced three days after admission, and she died on the fifth day. At the autopsy no signs of disease were found in other abdominal or genital organs. The heart showed a large vegetation on the posterior aortic valve, but no other valvular disease. Blood cultures on ordinary bouillon made on admission and two days afterwards were negative, but serum obtained on the day after admission produced marked agglutination in a typical laboratory culture of gonococci. The technique (Maurice Nicolle) is minutely described. Under the microscope the pericardial fluid, heart blood, and fragments of the vegetation removed aseptically at the autopsy all showed very numerous Gram-negative diplococci morphologically identical with gonococci; these were also found on section in scattered groups or in large masses in the partially organized granulation tissue of the vegetation from the aortic valve. No other micro-organism was found. Only one fragment of this vegetation yielded a growth on an ordinary medium; this was transferred to ascites agar and resulted in an abundant growth of typical diplococci. The authors consider that the occurrence of gonorrhoeal endocarditis, though rare, can no longer be doubted, and state that the lemon-yellow pericarditic effusion of moderate amount (in which they found numerous gonococci) is pathognomonic, and that the purulent pericarditis described by some authors is exceptional. They discuss the clinical symptoms and bacteriological findings and emphasize the statements of several observers—that blood cultures frequently fail; for this reason the agglutination test is preferred as being more reliable, enabling an earlier diagnosis to be made, when vaccine or serum therapy may arrest the disease before irreparable damage has resulted.

163. Emetine in the Treatment of Bilharzia Disease.

F. G. CAWSTON (*Journ. Trop. Med. and Hygiene*, May 1st, 1922, p. 112) emphasizes the efficacy of intramuscular injection of emetine for bilharziasis, as the result of an experience of over 300 injections of emetine hydrochloride. He states that where the doses are skillfully given and properly regulated this method of treating bilharzia disease is free from undesirable effect and is permanently successful in eradicating the infection; but on account of the slight cardiac depression caused by the large doses required by adults, the emetine treatment should be confined to children and young persons, and the pulse watched carefully throughout. The emetine salt is dissolved in boiling carbofic acid solution (1 per cent.) before injection into a muscle, and the dose of emetine hydro-

chloride given is from 1/8 to 3/4 grain according to age; injections should not be given more frequently than on alternate days. There is a risk that patients will consider that they have had enough treatment when the macroscopic blood has disappeared from the urine, but microscopic examination of the urine must be employed to judge of the effect of treatment and to decide the regulation of doses. It is also important to test for albumin or other evidences of ipecacuanha poisoning towards the end of treatment. The usual duration of treatment is to give intramuscular injections daily for three days and then three times a week for three weeks. The solution must be prepared within half an hour of each injection.

164. Focal Infections.

GAUDISSART (*Arch. Méd. Belges*, March, 1922) under the above title discusses the researches of Schottmüller, Rosenow, and Billings, and states that they appear to have proved the "transmutability" of *Streptococcus viridans* into a diplococcus of the pneumococcus group. *Streptococcus viridans* was grown upon various media and the growths injected into the blood of experimental animals, producing a pneumococcal infection. Billings states that Forssner made cultures of *Streptococcus haemolyticus* on kidney tissue and in media containing renal extract; these cultures when injected intravenously invariably produced renal lesions, but this "elective affinity" was lost by subcultures on ordinary bouillon, and reappeared on addition of renal extract to the medium. Rosenow repeated his experiments on a larger scale in order to prove that the "streptococcus-pneumococcus" group acquire specific pathogenic affinity in focal infections and also in other organs. A remarkable table of Rosenow's results is given showing that streptococci isolated from a specific organ or tissue show a striking affinity for that organ or tissue—for example, forty strains isolated from cases of appendicitis reproduced that disease in 68 per cent. of cases, while cultures obtained from other sources produced appendicitis in 5 per cent. only of the experimental animals. The author inclines to the theory of selective affinity, rather than to the alternative of a systemic infection in which the streptococci are destroyed elsewhere than in the damaged organ. He enumerates the possible foci of primary infection, emphasizing the dangers of alveolar abscess and of acute or chronic tonsillitis. He quotes Billings as deprecating tonsillectomy during an attack of acute rheumatism, as it does not change the course of the disease, but in chronic cases brilliant results have followed tonsillectomy and dental operations; the latter, and drainage of infected accessory sinuses, have cured or relieved cases of acute nephritis; and Babcock has reported good results in chronic myocarditis after drainage of the bile ducts.

165. Aspirin as a Urinary Disinfectant.

P. GALLOIS (*Bull. Soc. de Théor.*, May 10th, 1922, p. 149) during the last six years has made use of aspirin in cases of enlarged prostate, and has found it to be the best of urinary antiseptics with the exception of *B. coli* auto-vaccines. He was first led to employ the drug by noticing that in a case of enlarged prostate in which aspirin had been given for the relief of sciatica the urine became clear on administration of the drug, but became purulent again when it was discontinued. The doses given were 1½ to 2 grams a day for a week or fortnight. Aspirin was sometimes combined with other drugs such as uroformin or boric acid in doses of 1 gram a day. No cases of intolerance for aspirin were observed.

166. A Peculiar Eruptive Disease in Infancy.

J. H. PARK and J. C. MICHAEL (*Amer. Journ. Dis. Children*, June, 1922, p. 521) record observations upon 21 cases of an unusual eruptive disease occurring in children, aged from 4 months to 2 years, 10 being boys and 11 girls. Abrupt in onset, with fretfulness and fever, reaching as high as 105°, for from three to five days, when it usually resolved by crisis, with the appearance of discrete macules from 2 to 3 mm. in diameter on the buttocks or sides of the neck. The rash rapidly spread, being most profuse on the trunk and less intense on the extremities, and presenting a morbilliform aspect; with occasionally slightly raised maculo-papules, either entirely discrete or confluent, and reaching its height in twenty-four hours, disappearing the next day without desquamation. No Koplik's spots occurred and no definite cause for the fever could be discovered, and there was no infectivity or recurrence. During the pre-eruptive stage a leukopenia and lymphocytosis occurred. Diagnostically measles was excluded by the absence of contagion, catarrhal symptoms;

present the expectoration was unaffected. In 3 of the 6 cases in which there was fixation of the diaphragm the expectoration was relieved by the operation, in 2 it was not affected, and in 1 no note was made. In cases in which the diaphragm was movable expectoration was relieved in 20; and in no instance was it aggravated, and in 4 no note was made. Total paralysis of the diaphragm was present in 17 cases. Lange's conclusions are as follows: The expectations entertained as to the success of the operation have been fulfilled only to a moderate extent, although the indications for it have been considerably increased. The best results have been obtained in definite forms of tetanus, in constant clonic and tonic contractions of the diaphragm, and in those forms of pain in the shoulder which are due to the fibres of the phrenic nerve. According to Sauerbruch, phrenicotomy may be of great value in intrathoracic operations. In other diseases, such as pulmonary tuberculosis, bronchiectasis, empyema, and scoliosis, it does not possess much therapeutic value by itself, but only in combination with other measures. The symptoms resulting from unilateral and probably also from bilateral artificial paralysis of the diaphragm are slight compared with those of diaphragmatic paralysis produced by disease. Expectoration is relieved and bronchitis and pneumonia do not result. There is no appreciable effect on respiration and no circulatory disturbance. The operation, which is simple in its technique, may be regarded as harmless in its consequences.

173. Anomalous Abdominal Membranes.

TAYLOR (*Annals of Surgery*, May, 1922) finds that anomalous membranes are present in from 15 to 20 per cent. of newborn infants. They occur at the hepato-duodenal region, duodeno-jejunal angle, and about the caecum and ascending colon. They result from atypical peritoneal fusion in foetal life, and may become modified later owing to traction and inflammation. These membranes cause mechanical disturbances resulting in partial and often continuous obstruction, and as a result dilatation proximal to the obstruction. Symptoms may appear at any period of life, and not, as hitherto thought, only after 20 years of age; these develop when the obstruction becomes greater than the peristaltic efficiency can overcome. The symptoms consist of digestive disturbances, general nutritional disturbances, and neurasthenia. The appendix becomes tender owing to reflex action, and when removed there is no improvement. There may be dilatation of the stomach and caecum and tender spots over these areas. The most important element of evidence is found in the barium gastro-intestinal series; this may show a dilated and stosed stomach or a dependent and dilated duodenum. With a pericolic membrane the hepatic flexure shows high fixation with dilated caecum and ascending colon; the ileo-caecal valve is often incompetent and the appendix retains the barium for long periods. The treatment should be by medical means in the first place; when in spite of this the symptoms tend to become more continuous and severe, relief by surgery is indicated. The best incision is a transverse right rectus incision, as this gives the best exposure. Subsequently massage and a careful diet are given, and the results on the whole are satisfactory.

174. The Optic Nerve and Accessory Sinuses.

VAN DER HOEVE (*Arch. Ophthalmol.*, May, 1922), in considering the relation of optic nerve disease and affections of the accessory sinuses, points out that the optic nerve involvement is much more frequent in diseases of the posterior than of the anterior sinuses, and that the origin of a retro-bulbar neuritis cannot be determined by the signs in the eye. The diagnosis of sinus disease, especially of a posterior sinus, is often impossible, even with the aid of x rays, so that the only satisfactory method of excluding suppuration of those sinuses—the sphenoidal and posterior ethmoidal cells most likely to be causing serious orbito-ocular trouble—when x-ray examination is negative, is to open them up, since the absence of sinus affection cannot be definitely diagnosed otherwise. Sinus disease can affect the optic nerve by direct inflammatory extension, by the pressure of the balls of a dilated sinus, or by toxins, oedema, and congestion, the optic nerve changes being repairable or irreparable according to the degree with which the nerve has become affected by these agencies. When there is a sinus affection accompanying the optic nerve affection, many cases can be cured with a cocaine-adrenaline spray without operative interference, the difficulty as to the course to be adopted arising in those cases of optic nerve disease presenting no signs of sinus disease. Further statistics are required as to the results of operation as they affect restoration of sight and damage to the nose, as against the results in those patients for whom no sinus operation is performed, in order to solve the question as to whether we should operate on the nasal sinuses in optic nerve disease of unknown origin.

OBSTETRICS AND GYNAECOLOGY.

175. Necrobiosis of Myomata.

P. BÉGOVIN (*Paris Médical*, June 17th, 1922, p. 503) distinguishes between ordinary microbial gangrene of polypoid or submucous uterine myomata, and aseptic gangrene, or necrobiosis, of interstitial or subperitoneal myomata. Anatomically the necrobiotic myoma frequently shows a characteristic wine-red colour, but may be green or brown; it is much softened, particularly towards the centre, which may show cystic cavities. Microscopically various degrees of necrosis are shown in different tumours; the surrounding vessels and capillaries are dilated and engorged, and the adjacent tissue shows interstitial haemorrhages and sometimes venous thromboses. Necrobiotic tissue is completely aseptic. In explanation of the origin of the ischaemia which admittedly provokes the necrobiotic change Bégouin compares the condition with aseptic gangrene of the extremities or with focal cerebral softening, and points out that although all myomata possess a peripheral as well as a central system of arterial supply, in a large number the two systems are devoid of any anastomosis, so that arteritis with thrombosis, embolus, or even simple compression of the terminal artery supplying the centre of a myoma will suffice to induce necrobiosis. Clinically necrobiosis is frequently characterized by the following syndrome: pain, sudden increase of volume of the tumour accompanying sudden softening of its consistency, and alteration of the patient's general condition. The pain may be very acute, slight, or even absent, but tenderness of the altered tumour is constant; the alteration of the general condition is manifested as a rule by pyrexia, and often by a somewhat characteristic yellowish coloration of the face. Prognosis is good, largely because acute onset of necrobiosis usually leads to speedy operation, which is not rendered more difficult nor more precarious by reason of the alteration of the tumour. Delay in operating may lead to grave deterioration of the patient's condition as a consequence of intoxication, or more rarely to infection and suppuration. Coexistence of pregnancy, during which necrobiosis is relatively more frequent, does not contraindicate operation. As a rule hysterectomy should be done, but myomectomy may be possible in early instances of degeneration of subperitoneal myomata. During pregnancy if the foetus is viable hysterectomy is preceded by a Caesarean operation.

176. Menorrhagia due to Haemophilia.

MEUMANN (*Zentralbl. f. Gynäk.*, April 15th, 1922) records the case of a 2-para, aged 29, admitted to hospital on account of profound anaemia and intractable menorrhagia of twelve years' standing. Evidence that the condition was due to haemophilia was found in the family history, in the personal history of repeated epistaxis, frequent spontaneous subcutaneous ecchymoses, and alarming bleeding during each labour. Examination showed purpuric patches and a small adnexal tumour, diagnosed as a haematoma of the corpus luteum. The uterine haemorrhage, which did not respond to treatment by injections of pituitary extract or horse serum, was brought to a standstill by dilating the cervix by means of a tent and applying a solution of ferric chloride to the endometrium; the menorrhagia was subsequently controlled by calcium therapy. Haemophilia as a cause of menorrhagia is said to be exceptional, in that in most families of bleeders the morbid subjects are males and the females act as transmitters. In the family of Meumann's patient the male members were healthy but transmitted the haemophilic tendency to certain female descendants, and the patient's brother suffered from red-green amblyopia.

177. The End-results of Abdominal Caesarean Section.

IN 117 abdominal Caesarean sections performed at the Charity Hospital of New Orleans (excluding the Porro cases), there were twelve deaths from peritonitis and two from sepsis; all of these patients had had vaginal examinations or attempts at delivery before operation. The majority of all seventy-six patients recovering had fever, the puerperium being absolutely afebrile in only seventeen. Of sixty Charity Hospital patients in whom subsequent pregnancy was possible, five have not become pregnant since, four have passed through normal labours, two were delivered by forceps after long second stages (one by the Scanzoni method for unrotated right occipito-posterior position), one has had a second Caesarean operation, two have miscarried, one returned with a ruptured scar, one died eighteen months after operation when six months pregnant, and forty-three could not be located. Of twenty-seven private patients (on whom thirty-three sections were performed), two were delivered normally, four had a second Caesarean section, one had three Caesarean sections, four were patients cared for in 1921 (in whom subsequent pregnancy is as yet hardly possible), one sustained a

ruptured scar at subsequent labour, five died (one after her second Caesarean section), and ten in whom subsequent pregnancy was possible have not been traced. Six cases of ruptured placenta are reviewed by E. L. KING (*Journ. Amer. Med. Assoc.*, July 8th, 1922). He believes that the indications for Caesarean section should be restricted rather than broadened. In obstetric teaching, more and more stress should be laid on the importance of careful polytomy and of the early detection and proper treatment of toxæmia. Craniotomy or omphryotomy on the dead baby may be resorted to more frequently; pubiotomy may occasionally be employed, and the use of the Porro operation may be advantageously extended in infected cases. The low extraperitoneal operation, through the lower uterine segment, or partly through this structure and partly through the upper portion of the cervix, bids fair to become the operation of choice in the great majority of cases in which there is infection, especially if its claim to a lower percentage of subsequent rupture of the scar is borne out by experience.

178

Pathogenesis of Myomata.

ROSNER (*Gynæcol. et Obstét.*, 1922, v, 5) in previously published studies found that of 450 gynaecological patients 39 per cent. showed signs of constitutional subnormal development of the genital organs. More recently he has found that 22 per cent. only of myomatous patients come within this category, so that constitutional genital hypoplasia does not appear to favour the myomatous change. The reverse of this has been claimed to be true on the grounds that myomata are frequent among nulliparae and that sterility is most common in connexion with hypoplasia of the reproductive organs. Examining a series of 100 nulliparous patients, who had menstruated during twenty years, Rosner found that no fewer than 49 were myomatous; of the patients with genital hypoplasia 24 per cent. had myomata, but of others 78 per cent. were myomatous, and in this group the mean size of the tumours was considerably greater. On the grounds of these observations the writer concludes that (1) about one-half of women, who in spite of having menstruated for twenty years have had no children, uterine myomata are present; (2) if such women be classified according as the genital organs show normal or hypoplastic conditions, the former class show more frequently the presence of uterine myomata, and these as a rule are of larger size than in the latter class.

PATHOLOGY.

179.

Fatal Anaphylaxis in Man.

H. R. DEAN (*Journ. of Pathol. and Bact.*, July, 1922, p. 305) gives an account of the histology of a case of anaphylactic shock occurring in man. The patient was a soldier, aged 22, who had been wounded in the back and shoulder. He had previously received three doses of antitetanus serum without provoking any symptoms. The fourth dose, of 500 units, was given after an interval of twelve days, and almost immediately he called out that he felt very ill, and became cyanosed and began to vomit. In spite of injection of stimulants, massage, and artificial respiration, he died seventy minutes after the injection. The man had been apparently healthy until the day of his death, and all his wounds had completely healed. Death seemed to result from the fall of blood pressure and cardiac failure. It was found at the autopsy that the liver had a deep purplish colour and appeared to contain an excess of blood. Sections showed an extreme dilatation and engorgement of the sinusoids, and in spite of the short time which had elapsed since the injection many of the liver cells appeared to be swollen and empty, and in some the nucleus had disappeared. The lungs showed an irregular dilatation of the capillaries, and in some places the alveoli were compressed and in others dilated. There was enlargement of the lymphatic glands, which were more vascular than normal, and some showed an excess of fibrous tissue, but there was no trace of thymus tissue. The condition of the liver was very much the same as that found in acute anaphylactic death in dogs, so that it seems probable that in man also the primary and essential change is in the liver, and that the fall in blood pressure is the result of a dilatation of the capillaries of the liver. The capillaries of the liver contained enormous numbers of leucocytes, 12 per cent. of which were polymorphonuclear eosinophils.

180.

Milk Cows and Tuberculin.

A. CALMETTE (*Rev. d'hyg.*, May, 1922, p. 401) discusses the question whether milk cows which give a positive reaction to tuberculin should be destroyed. He states that in 1920 the total bovine population in France amounted to 12,757,720, of which it was estimated that no less than two million gave

a positive reaction to tuberculin. Similar statistics were published in Great Britain by Sheridan Delépine, who showed that the proportion of animals giving a positive reaction increased with age, the percentage under 1 year being 3.4 from 1 to 2 years 13.2, from 2 to 3 years 24.1, from 3 to 4 years 23.5, and from 5 to 9 years 48.9. A similar increase in the number of cases giving a positive reaction to tuberculin is met with in the human subject, but in neither instance does a positive reaction indicate the presence of slow tuberculous lesion or the liability to spread the disease. It merely shows the existence of a focus of infection which in the great majority of cases remains latent throughout life and often clears up altogether. Calmette comes to the conclusion that it is unjustifiable to forbid the sale of cows, which have no obvious clinical lesion, whose milk does not contain tubercle bacilli, and whose general condition is satisfactory, on the ground that they give a positive reaction to tuberculin. If such a practice were carried out the production of milk in France would be reduced by one-third; with deplorable results for the feeding of children.

181.

Researches on the Value of Antibodies in Tuberculosis.

THE antibodies studied by ARMAND-DEILLE, HILLEMANN, and LESTOQUOY (*Bull. Soc. Méd. des Hôpitaux de Paris*, June 8th, 1922) were those concerned in the fixation of complement; they were vitiated by the method of increasing doses of alexin, using a methylic antigen. The reaction was performed on 177 tuberculous patients in various stages of the disease; of these no fewer than 85 per cent. gave a positive reaction—a figure which is in fairly close accord with those given by other workers. It was further found that the reaction was positive in 5 out of 11 perfectly healthy individuals, and in 5 out of 8 patients who were suffering from non-tuberculous affections. From a diagnostic standpoint it would appear that the complement fixation test is of little or no value. Can it be used for prognosis? To determine this point the authors made repeated examinations on the same patients; taking very severe cases, it was found that in some there was an increase, in some a decrease, and in others merely an irregularity in the titre of the antibodies. Similarly with improved and with stationary cases. No correlation could be established, in fact, between the progress of the patient and the antibody titre of his serum. They conclude by issuing a caution against the rash interpretation of the reaction—a warning which was amply endorsed in the discussion which followed on the reading of their paper.

182.

Blood Cholesterol in Syphilis.

A. R. MCFARLAND (*Arch. of Derm. and Syph.*, July, 1922, p. 39) was led to study the quantity of cholesterol in the serum of syphilitics by a consideration of the fact that alcoholic extracts plus cholesterol have been proved to be the best antigens for the Wassermann reaction, and also because the *Spirochaeta pallida* readily attacks tissues rich in cholesterol, such as the central nervous system and liver. It has been shown that in other diseases, such as pneumonia and empyema, the blood cholesterol is low during the period of invasion, but increases as convalescence takes place; in many other diseases the cholesterol content of the blood appears to be an unassociated factor. The results derived from a positive Wassermann reaction showed a normal cholesterol content or one even below the average. A possible explanation for this may be that cholesterol as an agent of defence is low in chronic disease like syphilis, just as leucocytosis is low in chronic

syphilis of the nervous system, however, showed a large proportion of high cholesterol estimations, and this apparent increase in cerebral syphilis was the only recognizable relation between the clinical type of syphilis and blood cholesterol values.

183. Effect of Removal of the Liver on the Blood Sugar.

F. C. MANN and T. B. MAGATH (*Arch. Intern. Med.*, No. 1, Vol. 30, July 15th, 1922 [U.S.A.], p. 73) record the results of their experiments on dogs, with respect to the effect of removal of the liver on the blood sugar. These results are carefully considered, and the authors draw the following conclusions: There is a marked and progressive decrease in the blood sugar following total removal of the liver. The glycogen content of the muscles also decreases. Coincident with this decrease in blood sugar characteristic symptoms develop and progress until death. Removal of the liver also produces a marked decrease in blood sugar in other animals (dog, goose, turtle, and fish).

Observations

THE SIGNIFICANCE OF RETINAL HAEMORRHAGES.

BY
C. O. HAWTHORNE, M.D. GLASG., F.R.C.P. LOND.,
CONSULTING PHYSICIAN, CENTRAL LONDON OPHTHALMIC HOSPITAL.

As, in a generous but perhaps unduly sanguine mood, the Master of the Congress and his colleagues have placed in my hands the responsibility of opening this discussion, I must conclude that in their judgement it will be an advantage to have a statement of the problems affirmed by the existence of retinal haemorrhages as these present themselves in the practice of a physician. The issue arises in two different circumstances: (1) when, in consequence of the discovery of one or more haemorrhages in the retina, there appears the question whether these are of purely local significance or whether, on the contrary, the haemorrhage is an announcement of some diseased condition either affecting the body generally or situated in some more or less remote organ; and (2) when, the patient's health being in one fashion or another admittedly unsatisfactory, the recognition of retinal haemorrhage imposes itself as an additional fact, and one that demands consideration in the discussion of the diagnostic and prognostic aspects of the case. In the one instance the question is, is there, in addition to the retinal haemorrhage, any other evidence of disease, and if so, what is the relation between the two observations? In the other, What aid or influence does the retinal haemorrhage contribute to the clinical interpretation of the facts taken as a whole? Both in the one position and in the other it is obvious that a retinal haemorrhage in its clinical meaning can be judged only when all the facts—positive and negative—relative to the individual patient have been duly collected and studied; in other words, it is a claim for nothing less than a complete and thorough clinical examination. Not that in this respect retinal haemorrhage stands in a peculiar or exceptional position:—On the contrary, it comes under the general rule that, important as an examination of individual organs may be, still more important is the examination of the patient.

The first question in our discussion must necessarily be, May retinal haemorrhage exist without clinical significance? The answer, I think, must be in the affirmative. That is, routine ophthalmoscopic examination now and again discovers retinal haemorrhage in quite exceptional circumstances; and the circumstances are so various, and the event itself so occasional, that it seems impossible to attach to such haemorrhages any precise meaning and value. In my own notes I find records of retinal haemorrhages—few in number and slight in degree—in individual cases of pneumonia, pyonephrosis, malignant disease of the viscera, mitral disease, and ill-defined clinical conditions that had to be content with such an unsatisfactory label as "anaemia." As the routine use of the ophthalmoscope becomes more general under the influence of the conviction that inspection of the fundus oculi is an essential part of every complete clinical examination, it may be anticipated that unexpected retinal haemorrhages in various circumstances will be a more familiar experience.

In a second group of retinal haemorrhages the significance is obvious. I refer to haemorrhages due to violence. Of the consequences of direct violence applied to the eyeball or to the skull I say nothing, as such cases have for many years been outside my experience; nor do I know anything directly of the retinal haemorrhages said to be frequently found in newborn infants. My reference is to what may be called general bodily violence or physical shock without evidence of injury to the head. Retinal haemorrhages may be observed in these cases, and they have this practical aspect—that as the defect of sight to which they may give rise may be postponed or delayed, the responsibility of the violence for this defect is apt to be contested unless the fundus oculi has been examined in an early stage of the case. The experience is one more argument for the routine use of the ophthalmoscope even when no local claim for this procedure seems to exist.

As a third group, I mention retinal haemorrhages so severe as obviously to endanger vision, yet not provoked by violence, and not accompanied by signs of organic disease in other parts of the body. The most characteristic members of this group fall into the class described by Mr. Eales of Birmingham in 1880; the patients, lads or young men, the victims of severe, perhaps recurrent, retinal haemorrhage in one or both eyes, but otherwise apparently healthy though often giving a history of more or less extreme epistaxis. Upon cases of this order I have no remarks.

First, records every patient is said to have shown a "trace," or "a faint trace," of albuminuria. Happily no individual observer, I take it, sees many of these cases, but in my own experience, limited in this respect as it is, I have not detected albuminuria, and I suggest the point as one upon which members might give the Congress the benefit of their observations.

Secondly, Mr. Eales described in the retina, in cases that he named examples of "temporary functional albuminuria," "white specks" . . . presumably from previous haemorrhages, the patients being males of 11 to 28 years of age. Now albuminuria in apparently healthy persons is a problem often presented to the physician, the question being, Is the albuminuria an expression of mere functional disturbance or is it a signal of organic renal disease? Personally I should say that one of the notes of functional albuminuria is the absence of retinal change, and retinal haemorrhages or "white specks" . . . presumably from previous haemorrhages "would make me hesitate at so innocent a diagnosis. There must be, I imagine, many members of the Congress who have been asked to report on the ophthalmoscopic facts in case of albuminuria of more or less uncertain significance; and experiences gathered in this direction would, I am sure, be a valuable contribution to the present discussion.

My third remark is: If the essential note of Eales's disease is retinal haemorrhage unprovoked by violence and unaccompanied by evidences of organic change, then it will be very difficult to confine this name in any scheme of logical classification either to youthful patients or to the male sex. For, undoubtedly, retinal haemorrhage, strictly under the conditions just defined, occurs in middle-aged and even in elderly persons; and some of the victims are women. In other words, while the most extreme and disastrous examples of what may be called spontaneous or unexplained retinal haemorrhages are found in young men, this fashion of haemorrhage is not restricted to the earlier years of life; nor is it confined to the male sex. If a line of division is to be drawn between true cases of Eales's disease and other cases of apparently spontaneous retinal haemorrhage, I ask members of the Congress to say exactly where it is to be drawn. The difficulty is a real one. It is illustrated, to take but a single example, in a paper written some years ago by Mr. Leslie Paton and Dr. Erasmus Paramore, where, in a short series of unexplained haemorrhages, the writers include two women; one aged 27 years and the other 34 years. The point is one that seems to invite discussion.

At first sight it might appear that uncomplicated and unexplained retinal haemorrhage forms purely an ophthalmological problem. But really it is not so. On the contrary, it occupies merely one page of a fairly considerable chapter. For haemorrhages apart from violence, and unaccompanied by appreciable organic change, occur in almost all parts of the body. Epistaxis, for example, without nasal lesion is so well known that its occurrence is little more than a mildly exciting domestic incident; haematemesis does not always mean ulceration of the gastric or duodenal mucous membrane; there are cases of haematuria, not infrequently recurrent haematuria, in which no structural alteration can be found in the urinary passages; even haemoptysis sometimes stands in a similar enigmatic position; and cerebral and cerebellar haemorrhages in adolescents are by no means altogether unknown. Thus retinal haemorrhages existing as an isolated clinical event have their parallels if not their explanation. An explanation is indeed difficult. So far as I have followed the discussion the key seems to have been sought in one direction, and in one direction only—namely, in an attempt to determine an alteration in the coagulation rate of the blood. The results have not been encouraging, for, while on one side it is announced that coagulation is hastened, we hear from other quarters that coagulation is delayed; and the confusion is increased by a

* Introduction to a discussion at the Oxford Ophthalmological Congress, July 6th, 1922.

1 See Sir Wm. Hale-White, *Lancet*, 1912, i, p. 416; and Professor George R. Murray, *British Medical Journal*, 1913, ii, p. 1521.

third statement to the effect that no departure from the normal can be appreciated. With all respect I dare to say that even were this point finally and authoritatively settled we should still be without an explanation of the haemorrhage. For, while the readiness, or the difficulty, with which the blood coagulates must be a large influence in determining the volume or duration of a haemorrhage, no modification in either of these directions will account for the actual occurrence of haemorrhage. To produce this there must be rupture of vessels, and rupture of vessels, in the absence of violence and of increased intravascular stress—and neither of these factors is in issue here—can only follow changes (nutritional or structural) in the vessel walls. It is therefore in the direction of agencies calculated to damage the walls of the vessels that an explanation of these quasi-spontaneous retinal haemorrhages must be sought. There are here two considerations which may appropriately be borne in mind.

First, it is beyond doubt that the walls of the finer blood vessels are particularly susceptible to the influence of pathological changes in the blood quality; and it would seem that in at least many of these changes each has its special or selected area of mischief. Thus in typhus we get haemorrhages in the skin; in scurvy, in the gums; in Menoch's purpura, in the intestinal wall; in influenza, epistaxis; and in cantharides poisoning, haematuria. Evidently in each of these instances the blood vessels in a particular area have been damaged by a poison that has to the affected vessels a specific pathological relationship. Is it not probable that in similar fashion the retinal blood vessels, or the retinal blood vessels in some persons, may be damaged by modifications of the blood quality that are at present beyond our power of detection and recognition?

A second influence possibly related to these spontaneous retinal haemorrhages is that the blood vessels in different persons possess different degrees of fragility. In some a mere friendly grasp of the arm is followed by ecchymosis, while in others a much greater degree of violence is necessary to produce a bruise. Once again, may it not be that there are individuals in whom the retinal vessels are unduly fragile as the result either of an inherited peculiarity or of an acquired defect, and that upon such vessels minor and perhaps unperceived degrees of violence act with disastrous consequences?

Summing up, therefore, this part of the discussion, I submit the following propositions: That retinal haemorrhages existing as an isolated clinical fact are strictly parallel to other haemorrhages which occur in various parts of the body apart from obvious violence and without appreciable organic lesion; that a departure, even if it exists, from the normal rate of blood coagulation will not account for these haemorrhages; and that the probable explanation is rupture of vessels following damage to their walls, this damage in turn resulting either from some subtle change in the blood quality or from slight degrees of violence—perhaps mere changes in intracranial tension—acting on vessels which for one reason or another are particularly susceptible to the destructive influence of mechanical forces. Possibly it may be suggested that the event immediately antecedent to the haemorrhage is thrombosis; and this may well be true. But thrombosis in its turn requires an explanation, and it may be doubted whether intravascular blood-clotting ever occurs in vessels which possess a healthy and undamaged endothelial lining. So that once again there is need for prior damage, nutritional or mechanical, to the vessel wall. Given this, either direct rupture is conceivable, or thrombosis, this latter establishing circulatory conditions which mean a breach in the integrity of the vessel and the escape of the fluid contents into the neighbouring tissues. In a word, whether the rupture immediately responsible for the haemorrhages is direct or is secondary to thrombosis, there is necessary as an antecedent event some preliminary prejudice to the anatomical or physiological values of the vessel wall.

I now propose to find support for the order of events just suggested—that is, damage to the vessel wall, thrombosis, suggested—in the retinal haemorrhages (a well-known class) consequent on thrombosis of the central retinal vein. I have had the opportunity of examining for my surgical colleagues a considerable number of cases of this order, and with three exceptions (to be mentioned later) the patients have been elderly—50 years and upwards—and have exhibited evidences, and often conspicuous evidences, of cardio-vascular degeneration—thickened and deformed arteries, high sphygmometer readings, left cardiac hypertrophy, and sometimes albuminuria, though rarely convincing signs

of nephritis. Here, then, we have manifest and undeniable evidence of structural alterations in the vascular apparatus, and even apart from actual pathological demonstration—and this is by no means wholly wanting—there is a moral certainty that with evident arterial degeneration changes of a similar order will be present in the walls of the veins. Upon such damaged areas clot formation may readily be implanted, with, as a natural consequence, blocking of the circulatory movement, further prejudice to the vessel wall, rupture, and haemorrhage.

It may, however, be said that the argument here presented cannot apply to the occasional cases of thrombosis of the central retinal vein occurring in young persons free from obvious vascular disease and offering normal or approximately normal sphygmometer readings; and it must be admitted that in such cases we cannot claim the overt evidence of vascular disease seen in elderly persons affected by retinal venous thrombosis. On the other hand, it is certain that young persons are not altogether free from the risk of thrombosis, as is seen, for example, in the case of chlorotic girls. Such thrombosis must be either primary—that is, spontaneous—or secondary to changes in the vessel wall at the site where the clot formation takes place. But spontaneous intravascular blood-clotting is, for reasons already given, highly unlikely. Hence it seems necessary to admit that even when objective evidence of change in the vascular structures is wanting the occurrence of thrombosis implies that such change as a fact has actually taken place. In other words, retinal venous thrombosis, in the younger patients as in the elderly, is secondary to some fashion of alteration in the vessel wall. My suggestion, therefore, is that such cases form, as it were, a connecting link between the group of unexplained haemorrhages already considered, and the cases of retinal venous thrombosis as this is more commonly seen in elderly patients. In all, I assume as the primary event pathological changes in the vessel walls, and following these changes either direct rupture or thrombosis prior to rupture. The groups, however, differ from one another in the site of the preliminary vascular damage and in the degree of clinical evidence available for the recognition of this damage.

I now pass to retinal haemorrhages—other than those consequent on retinal venous thrombosis—found in association with high sphygmometer readings. Personally I speak of "high sphygmometer readings" rather than of "high blood pressures," for the sphygmometer reading is a fact, whilst its translation into terms of blood pressure involves an inference, and an inference, moreover, which has not wholly escaped an accusation of inaccuracy. If in scientific terminology names having a descriptive quality are selected, clearly they should be descriptive of facts and not of opinions about facts. Our immediate point, however, is the significance of retinal haemorrhages in patients yielding high sphygmometer readings. This group is a fairly considerable one; but its constituent members differ widely from one another both in character and in outlook. At one extreme are cases of renal disease without dropsy—the so-called small white kidney—occurring in young adults, often marked by epistaxis, and leading almost invariably in the course of a few months to a fatal issue. At the other extreme is a single haemorrhage in, say, a middle-aged or elderly patient, possibly destructive of central vision in the affected eye, but, as proved by the subsequent course of events, quite consistent with health and activity prolonged over a considerable term of years. And between these two extremes lie various degrees and gradations of arterial change and various degrees and gradations of renal mischief. In either extreme, as well as in the intermediate cases, retinal haemorrhage may be the first event to attract attention, or the haemorrhage may be found on occurrence of retinal haemorrhage any vision.

render any substantial assistance in the differential diagnosis or in the prognosis of the members of this large and varied group? I doubt it. Guidance in these directions is to be sought, not in the presence or the absence of retinal haemorrhage but in the state of the heart, the condition of the arteries, and in the efficiency or non-efficiency of the renal excretory functions.

In connexion with this last-mentioned group of cases, it is well to remark that high sphygmometer readings, and even very high readings, by no means necessarily involve retinal haemorrhage; indeed, in the majority of cases of this order the fundus oculi is normal, or at least free from haemorrhage;

and this is true even when so disastrous an event as cerebral apoplexy is the commanding fact in the clinical picture. Thus it seems safe to say that retinal haemorrhages are not produced by the "bursting" of healthy blood vessels—or for the matter of that of degenerated blood vessels—under the stress of increased intravascular pressure, even allowing what is a disputed point—that a high reading obtained from the brachial artery means increased blood pressure within the retinal vessels. Retinal haemorrhages, as I have already argued, mean, indeed, rupture of vessels, but the essential cause of this rupture is, not increased intravascular stress, but degenerative changes in the vessel walls. Support for these propositions is found in yet another group of cases—namely, those in which there is manifest arterial degeneration without high sphygmometer readings; for in such cases retinal haemorrhages may be present—may be present, that is, when, at least so far as the sphygmometer can be trusted, the blood pressure is not abnormal. In other words, high sphygmometer readings—or, if you will, high blood pressures—do not *per se* involve vascular rupture, while vascular disease may lead to rupture even when the alleged measurement of blood pressure is well within normal limits. It is change in the valno of the vessel wall that is the necessary preliminary to rupture and haemorrhage, and this change either may or may not be associated with a high sphygmometer record.

Perhaps here I may be allowed a word in appreciation of the work done by ophthalmic surgeons on the pathology and clinical evidences of degenerative disease of the blood vessels. It has helped towards the solution of not a few obscure problems.

Of retinal haemorrhages in glycosuria there is little to be said. They are found, as everyone agrees, not in the typical diabetes of the earlier years of life but in middle-aged or elderly persons with slight or moderate symptoms and non-extreme degrees of glycosuria. They may or may not be accompanied by retinitis. When, as sometimes happens, the glycosuria disappears for a more or less prolonged interval the ophthalmoscopic picture may be a very puzzling one for an observer ignorant of the patient's earlier history. Upon prognosis in glycosuria retinal haemorrhage as such exerts little or no influence; the haemorrhage is quite consistent with active life continued during many years.

In the course of our discussion we are likely to hear of the differences—the diagnostic differences, as some affirm—between retinal haemorrhages in glycosuria and retinal haemorrhages in albuminuria. I admit the interest of the comparison as a subject for ophthalmoscopic contemplation and as an opportunity for the cultivation of the sporting spirit in the art of diagnostic adventure. But the observation has little clinical value. At best the conclusion suggested is a probability, and a probability which no one will say is invariably justified by the event. Moreover, the procedure is an offence against a sound and sensible rule—important in medicine as in law—that second-rate evidence ought not to be accepted when first-rate evidence is available.

I have now briefly to refer to certain clinical situations in which the discovery of retinal haemorrhages has a high practical value, inasmuch as such a discovery may save the practitioner from error and may indicate the route along which an accurate diagnostic conclusion is to be sought. Experiences of retinal haemorrhages as the first clinical event in renal disease, in glycosuria, and in arterial degeneration, are obvious illustrations of this proposition. A few others may be mentioned.

First, a doubtful or ambiguous appearance at the optic disc will be confidently interpreted if the suggestion of a possible commencing optic neuritis is accompanied by one or more small linear haemorrhages. They may require close observation, but once detected there can be no question of their significance.

Next I mention septicaemia and septic endocarditis. Quite a number of such cases are clinically, and for a more or less prolonged period, cases of unexplained temperature—fever without physical signs; and such diagnoses as tubercle, enteric fever, paratyphoid, and *Bacillus coli* infection of the urinary passages come up for discussion; or, again, with the fever are joint pains, and acute rheumatism offers itself as an appropriate label; and once more, in a patient known to be the subject of a chronic valvular lesion occurs an outbreak of febrile temperatures, and a recrudescence of active rheumatism is a tempting explanation. Yet in every one of these instances an ophthalmoscopic examination may promptly and confidently alter both the diagnostic position and the prognostic

outlook, for retinal haemorrhages are not to be expected either in tuberculosis, or in enteric fever, or in paratyphoid, or in *B. coli* infections, while in septicaemia and in septic endocarditis they are quite frequent events.

Another disease in which the presence of retinal haemorrhages affords much help is pernicious anaemia. Here again, though rarely I admit, the problem presents itself in the form of unexplained pyrexia, and the anaemia and weakness are readily regarded as consequences of the high temperature, and for this an explanation is sought in the directions already indicated; the detection of retinal haemorrhages in such circumstances is of great practical value. On the other hand, a more or less severe and prolonged anaemia may be attributed to chlorosis, to dyspepsia, to malnutrition, or to some other more or less indefinite influence. The recognition of retinal haemorrhages here ought to sound a note of alarm, for such haemorrhages are frequent in pernicious anaemia, whereas in chlorosis and in secondary anaemias they are either absent or, if occasionally present, are slight in degree, few in number, and confined to extreme and advanced cases. Even a wider generalization may be ventured—namely, that retinal haemorrhages in the absence of renal disease, of glycosuria, and of arterial degeneration mean either sepsis or one of the so-called blood diseases, and particularly pernicious anaemia and leukaemia. Rarely they are due to malaria, and very rarely to syphilis; personally, I have not seen them in haemophilia or in Hodgkin's disease, and only once in purpura haemorrhagica. Retinal embolism and thrombosis of the retinal vessels perhaps ought to be mentioned, but in each of these there are in the history and in the ophthalmoscopic examination characteristic facts which reduce the attendant haemorrhages to a purely subordinate position. In addition, the generalization just proposed is qualified by the "unexplained" haemorrhages to which reference has already been made, and by the necessary remark that propositions which pretend to absolute values in the field of clinical medicine, however serviceable for general guidance, are apt now and again to suffer in their dignity by the arrival of events and combinations which contradict them.

In a congress of ophthalmic surgeons it would be gratuitous to insist on the importance of examining each fundus oculi, and yet it may be well to remark that even in so generalized a disease as pernicious anaemia retinal haemorrhages may have, at any rate for a time, a purely unilateral distribution.

CONCLUSIONS.

Finally, I submit the following practical conclusions—namely:

1. That retinal haemorrhages may exist without recognized prejudice to vision, and ophthalmoscopic examination is therefore a necessary part of every clinical examination.
2. That such haemorrhages may be the first objective signs of serious disease, and a discovery of them, therefore, demands a complete examination of the patient.
3. That the recognition of retinal haemorrhage is often of high value in directing the observer to a correct interpretation of the clinical facts, while the prognostic significance of the observation *per se* is indeterminate.
4. That retinal haemorrhages do occasionally exist as isolated clinical facts, and when so existing are comparable to haemorrhages in other parts of the body (haematemesis, haematuria, haemoptysis, etc.), for which no ready explanation is at hand.

A METHOD OF REDUCING CONGENITAL DISLOCATION OF THE HIP.

BY

F. W. GOYDER, F.R.C.S.,

HONORARY SURGEON TO THE BRADFORD ROYAL INFIRMARY.

Reduction of a congenital dislocation, except in very young children, is not always the simple matter described in the textbooks. When the ordinary methods of pulling, lifting, and levering are employed the operator works under mechanical difficulties, and, unless well equipped physically, is likely to fail. So much energy is expended in pulling that proper control over the movements of the head of the femur is lost, and if the help of an assistant be utilized there is often want of complete co-ordination between the manipulators. In any case much energy is wasted. The method here described appears to me to avoid misdirected effort and

to put the movements of the head of the femur completely under the control of the operator. I can find no procedure exactly like it mentioned in the literature, except perhaps Hoffa's "pump-handle" method, but the idea seems so simple that it must have been tried before. Even if it is not now, I can claim to have discovered it for myself.

It requires some strength to pull the head down to the level of the acetabulum, and more strength to maintain it there. It occurred to me, therefore, that it might be much easier to push than to pull, and that if I could, by downward pressure of one hand on the fully flexed knee, push the head below the ill-marked lower rim of the acetabulum, I might with the other hand guide the head into the socket. I was surprised at the control so gained, and at the amount of downward pressure possible.

The method adopted for the left hip is as follows: The patient's sperm may be placed on a sandbag; the pelvis on the right side must be steadied by an assistant. The knee and hip are flexed, the latter as fully as possible till the knee lies as nearly as can be managed beside the trunk. The right hand of the operator is put upon the patient's left knee and has two functions—first, by downward pressure to push the head towards the acetabulum, and secondly, by rotation at the knee to direct the movements of the femoral head. The palm of the operator's left hand is placed against the great trochanter with the thumb in front and the fingers on the neck of the femur behind. While downward pressure is maintained with the right hand to keep the head of the femur as low as possible an attempt is made, by lifting with the fingers of the left hand, and depressing the right hand with or without rotation, to put the head below the acetabulum. A little time and some preliminary stretching of the tissues below the acetabulum may be needed, but no great force. The next manoeuvre consists in maintaining the forward position of the head while gradually relaxing the pressure on the knee, when the head sinks noiselessly into the acetabulum, often at the first attempt. This done, external rotation at the hip-joint brings the limb into the usual Lorenz position. The thigh should usually be approximately at right angles to the body, and the knee more dorsally placed than the pubic symphysis, so that the head of the femur is fairly prominent in the groin. Reduction should be repeated a few times, noting the degree of prominence of the posterior and superior margin of the acetabulum by the "shock" of redislocation, and the amount of movement possible at the hip-joint without producing redislocation. It will often be found at this stage that reduction has become possible by the more usual method of lifting the head of the femur over the posterior lip of the acetabulum.

The considerations just given appeared at first sufficient in themselves to account for the success of the manoeuvre, but an additional explanation of the comparative ease of reduction by this method was afforded by a short but important paper by Mr. A. H. Tubby, published in the *Lancet* of December 20th, 1919, describing an open operation for refractory cases. He emphasized the fact that in older children the ilio-psoas tendon is, after the adductors, the greatest bar to reduction, because it produces a virtual, and in late cases an actual, narrowing of the capsule of the hip-joint where the tendon crosses. This constriction prevents the head from passing through the "button-hole" in the capsule and lodging in the acetabulum. The tendon divides the capsule of the dislocated hip-joint into two communicating cavities—an inner one, of which the acetabulum is a part, and an outer one containing the head of the femur. Full flexion in my method relaxes the grip of the tendon; downward pressure puts the head of the bone to the acetabular side of the relaxed ilio-psoas, and, unless there is real narrowing, relaxation of downward pressure allows the head to enter the acetabulum without the intervention of the folded capsule of the hip-joint. It is important to remember that the success of reduction by this method does not necessarily obviate an open operation, because when the leg is extended the tendon again becomes tight, perhaps sufficiently so to cause redislocation. But that point does not apply to the more limited purpose of this paper.

I have found this method of the greatest value in neglected cases of congenital dislocation. It renders unnecessary long-continued extension of the limb and excision of portions of the adductors and other muscles. In younger children it may avoid a preliminary division of the adductors. Hence I commend it to all who have encountered difficulties in reduction by the well-established methods.

FRAGILITAS OSSIUM ASSOCIATED WITH BLUE SCLEROTICS.

BY

HALL STEWART, M.B., B.Ch., D.P.H.,
HOUSE-SURGEON, ULSTER HOSPITAL FOR CHILDREN AND WOMEN, BELFAST.
[With Special Plate.]

The publication of Dr. J. B. Alexander's paper on "Fragilitas ossium associated with blue sclerotics" in the *BRITISH MEDICAL JOURNAL* of April 29th, 1922, leads me to report the following series of cases:

Case 1.—L. G., a girl with blue sclerotics, aged 7 years, has been treated in this hospital on different occasions for ten complete fractures. She was first admitted in 1917 when fracture of her left femur, and since the following fractures: right femur, right tibia, one complete and one greenstick; right humerus, two complete; right tibia, one complete and one greenstick.

Case 2.—T. McV., a boy with blue sclerotics, aged 2 years, half-brother of L. G. (Case 1), is at present in hospital suffering from a fracture of his right femur.

Case 3.—T. R., a boy with blue sclerotics, aged 7 years (cousin of L. G. and T. McV.), has had six fractures of his leg bones. In 1917, when 2 years old, he was admitted to this hospital with his right tibia and fibula broken. Since that time he has been treated for the following fractures: right femur, two complete; right tibia, one complete; left tibia, one complete; right fibula, one greenstick.

These three children are poorly developed and have prominent foreheads. The only other member of the family to which Cases 1 and 2 belong is a female infant, aged 5 months. She also has blue sclerotics.

The broken bones united at about the normal rate. Union was firm, though callus formation was scanty. X-ray photographs showed the cortex of the bones to be excessively thin and the medulla somewhat diffuse. The fathers of these children showed no apparent abnormality.

The mother of L. G. and T. McV. (Cases 1 and 2) has blue sclerotics and has suffered from partial deafness since childhood. She gives a history of having had her right femur fractured on two occasions. The first fracture occurred when 2 years old, and the second two months later. She has seven sisters and two brothers, all younger than herself. None of them suffer from undue fragility of their bones. The three eldest of these are females, and have blue sclerotics. The second member of the family is the mother of T. R. (Case 3).

The relation of these individuals to each other is shown in the following tree:

The points of interest in this series of cases are:

1. The four eldest members of the family have blue sclerotics; the children of the two eldest suffer from fragilitas ossium and blue sclerotics, while the children of the third are apparently normal. The fourth sister, who died some years ago, was unmarried.
2. The great preponderance of right-sided fractures.
3. The leg bones are chiefly affected.
4. The first fracture in each case occurred at 2 years of age.
5. Only one case of deficient hearing.
6. All cases with brittle bones have blue sclerotics, but several cases with blue sclerotics have apparently normal bones.

I am indebted for access to these cases to Mr. S. T. Irwin and Dr. R. J. McCounell, under whose care they have been.

BEFORE the war the birth rate in Germany and the natural increase—that is, the excess of births over deaths—were greater in Germany than in this country. The death rate also was higher. The *Morning Post* has recently published some interesting statistics of the German rates in the second quarter of this year. For the forty-six great towns of Germany the birth rate was 18.5, whereas in England and Wales it was 22.2. For the same period the death rate in Germany was 13.5, and in this country 12.7. The rate of annual increase in England and Wales in the period 1904-13 was 11.2; in the second quarter of this year it was 9.5. In Germany before the war the rate was 15.1, but in the second quarter of this year it was only 5.

DISCUSSION ON OCCUPATIONAL DERMATITIS.

OPENING PAPER

BY

W. J. O'DONOVAN, O.B.E., M.D., M.R.C.P.,

First Assistant in the Skin Clinic, London Hospital.

[With Special Plate.]

STUDENTS of skin diseases, once they have mastered and appreciated its historic nomenclature, are stimulated in their work by the consciousness that cause and effect are demonstrated before their eyes in a manner paralleled only by the practice of Tropical Medicine. Preventive medicine, the keynote of to-day, is based fundamentally on accurate knowledge of etiology, and I appreciate that the Section in asking me to read a paper on Industrial Dermatitis is really paying tribute to an etiological factor recognized in dermatology but not pursued as it should be in this country, whose civilization and prosperity are now founded on industry.

It is fair to say that my hospital, the London Hospital, is favourably situated for an industrial study, since around it are grouped not one main type of industry, as in a mining centre or a fishing town, but hundreds of separate industries that employ their thousands resident about the hospital. The tonnage of the Thames and the barge transport of the Lea Valley bring within our ambit industries as far apart as fig pulping and explosives making. The proximity of the Home Office, too, is of importance to us in London, since without the kind and constant encouragement of Dr. T. M. Legge the collection of material for this special study would have flagged in the onrush of ordinary but overwhelming hospital dermatological work.

Technique of Study.

In the first place, every man or woman who comes to the skin clinic at the London Hospital is asked his or her occupation—not in general terms, but an attempt is made to find out their actual occupation, what they handle, what is the name of the acid or dye or wood they use, how long they have been at this, and whether other workers are similarly affected. When possible they are asked to bring for inspection a sample of the substances which may be the cause of their lesions, and, but rarely, we have been able to visit the factory, wharf, or workshop concerned. A record in writing is, of course, made of the nature and extent of the lesions, and their present state and progress are recorded by photographs—the only way of saving any skin department from the labour of interminable verbiage and for bearing which expense we (Dr. Sequeira and myself) are most grateful to the Governors of the London Hospital.

Industry is complex and technical, varying trade names cover identical formulae, and years of wide experience have made these details known and appreciated at the Home Office, whose mine of special knowledge I gratefully own is almost inexhaustible. A worker's knowledge of his own industry is often an empty ignorance—"chemicals," "drugs," "red dye" is often all the description he can supply of a substance he has handled for years; hence I have often found it necessary to write to a man's employers, and, should they fail, to the Factory Department of the Home Office, to find out what was the actual dye or other substance implicated.

Industrial dermatitis is not at present a wide field for compensation cases, and therefore truth-telling among workers, their unions, and their employers, is fortunately prevalent at present. Statistics we have not attempted to keep, since to be of value they must be complete and widespread in their

survey, and this can only be done by statutory notification. We ourselves make a habit of notifying all our interesting cases to the Home Office, in return for the help we receive and because we realize that these diseases cannot be prevented until their type and prevalence are recognized. We realize that prevention is best left in the hands of experts familiar with factory technique and managerial difficulties, the habits of the workers, and medical administration. I feel that this study is the type of observation on which prevention must be based, but that this prevention is no function of dermatological study.

In this paper I make no references to literature, which in English is very scanty, save for Prosser White's invaluable and pioneer guide-book, now in a second and much improved edition. I propose to attempt to add perhaps a little to knowledge by recording solely my own clinical experiences.

Friction: Hyperkeratosis and Cancer.

Two instances of local palmar keratoses have been seen.

A painter, aged 40, showed a triangular patch of dark, very thick, and fissured skin, having its base along the ball of the right thumb; this he had had for over fifteen years, and of late it had become sore and painful while at work. It was due to the constant, almost daily, use of a scraper held always against the right palm, while working with a blow-lamp in the left. His left hand was unaffected. The Wassermann reaction was negative. Temporary rest and salicylic acid ointment gave rapid relief. (See Fig. 4 in Special Plate.)

Mrs. R. P., aged 48, was a stout woman, by trade a boot-soler. Her work consisted of holding pieces of wet leather in her left hand and hammering it out with a short hammer held in the right hand. The constant rubbing of the short handle caused a great thickening of the palmar skin, which was sore, tender, and rough; its fissures were all deepened, widened, and excoriated, and she was unable to continue her occupation.

The connexion between occupational trauma and carcinoma could hardly be more beautifully illustrated than in the following case.

C. K., aged 65, an alien baker in the East End. For certainly over thirty years he had been employed in a small bakery, and for over ten years had noticed the development of a small wart at the middle joint of his left thumb, where a long and hot iron poker was continually rubbing during his daily work. For the last six months this wart had grown rapidly and ulcerated, and because of occasional hæmorrhage he had sought hospital assistance. A microscopic section from the edge (see Fig. 5) showed the growth to be a squamous-celled carcinoma. The patient refused operative relief.

The following is, as far as I can find, a unique case, but perhaps the experiences of the meeting may bring other wedding-ring carcinomata to light.

Mrs. W., aged 78, came to our clinic this year suffering from a squamous-celled epithelioma of the left ring finger; it had existed for twelve months, and extended for half an inch, as a nodular hard growth, above and below a shallow irregular ulcer in the site of her recently removed wedding ring. There were no enlarged lymphatic glands, the finger was amputated and she is now well.

A third case of what I would term friction carcinoma of the tongue.

G. H., a boot repairer aged 48, has repaired boots since the age of 18 and has always when at work held a supply of "brads" or small rivets of iron or brass in the right side of the mouth. He used to work them one at a time forward towards his lips so as to have one always to hand and so save time. For three months the right side of the tongue has been sore and painful. He could protrude his tongue easily and on the right side was a raised, firm, slightly ulcerated tumour, circular in shape, about the size of a shilling; the diagnosis of carcinoma was confirmed by the microscopic finding of prickly-cell processes in the tongue muscle. In addition the surface of the tongue showed a mild condition of superficial glossitis—it was mostly white, glistening, and smooth, with some transverse furrowing; there was no fissuring or erosion of the tongue generally, and it did not resemble the usual advanced syphilitic infiltration of the tongue on which carcinoma is only too common an epiphenomenon, but the Wassermann reaction was positive, and the patient was treated by both operative and anti-syphilitic measures. This is a case of local long-continued trauma producing a carcinomatous overgrowth in a tongue damaged, though slightly, by syphilis. The patient remembered a venereal sore when a young man, treated as a chancre, but not perseveringly.

After syphilis, tubercle.

H. K., a taxi driver, aged 44, has large sheets of long-standing lupus on his limbs, but he developed a carcinomatous ulcer on the front of his left wrist, where for years a lupoid dry patch of skin had

rubbed against the driving wheel. Six months of discomfort drove him to seek medical aid. He died under a general anaesthetic in 1920.

Dermatitis and Dirt.

Contrary to one's expectations dirty work in the ordinary use of the term does not particularly predispose towards dermatitis. Quite the dirtiest factory I ever visited was one employed in the breaking down of used or damaged anti-gas masks. The masks arrived in hundreds often covered with mud, dust, or blood-stained or stinking, and were separated into their components by scores of women without protective appliances or anything like adequate washing facilities. On the day of my visit there was no soap and the towels on view were dripping wet, yet save for an outrageous case of dermatitis artefacta no cases of sore hands occurred at this work. The cleaning and repairing of old sacks gives employment to many women about the hospital, yet only two cases have come before us in which the work could be held to be responsible.

G., aged 32, had an outcrop of large tense bullae on the hands, which was attributed to the work, which the patient said was very dirty. She showed bullae, varying in size from 2 mm. to 3 cm. across, on both sides of both hands, most being present along the outer border of the thumb; a very large one was situated across the centre of the palm. They contained either clear or turbid fluid, and small burst blisters showed adherent impetiginous crusts.

The mending of old sacks was attended with very serious ill effects in the case of Mrs. H. H., aged 52, who had worked at this from December 5th, 1917, until early in January, 1920. When seen on January 13th, 1920, the tips of all her fingers were red, sore, and scaling, and on the palmar aspects of her fingers were numerous closely set minute vesicles; all her nail-beds were infiltrated with pus, and she had shed two nails from her left and three from her right hand; no fungus was found on scrapings; red lines of lymphangitis were present on the right forearm with epirochlear adenitis.

Dirty work is common, yet dirt dermatitis is rare. Coal-mining is dirty work, yet "miners' itch" needs, in addition to coal dust, the maceration of the skin by standing in water at work. At a brass-rolling mills I examined in 1918 over fifty men blackened all over by a deposit of zinc dust sublimated from many crucibles in a room that was an inferno of heat and clouds of opaque metal fumes, yet though these men were unselected and had been at this work for over twelve months, I saw no dermatitis among them; yet by absorption zinc "bends" (or agues) were common amongst them.

Water Rashes.

As a strong antithesis to the above one can say confidently that occupations in which water comes into frequent or prolonged contact with the hands are attended with a very real hazard of dermatitis in either sex at any period of life. The addition of any cleansing agent, whether acid or alkali, adds notably to the risk.

A. P., a healthy male of 21, was a fishmonger's assistant, and had worked at this for over twelve months; he says his hands were constantly in running water but he did not handle brine. His hands when seen had troubled him with itching and soreness for about a week; they presented a beautifully symmetrical eruption of reddened excoriated papules aggregated into irregularly oval areas on the ulnar sides of the backs of both hands. This eruption cleared up in a week of rest from work and the application of calamine lotion, and, without inquiry into his occupation, would have been termed an eczematous dermatitis.

Four weeks later L. D., aged 18, came to the clinic with an eruption very much resembling that of A. P.—similar in distribution on the backs of both of her hands and extending up over the backs of the inner three fingers. Her trouble had come and gone at intervals over three years; during all this time she too had worked in a fishmonger's shop, handling wet fish throughout the day.

It is hard to associate the displayed enamel advertisements on the railway stations with an occupational risk, but the following case is evidence that such a risk exists.

T. W., aged 41, had had no skin trouble until in destitution he accepted the job as a cleaner of these signs; for three months he had been at this work, using as a rule water only, but when the dirt was very adherent it was his habit to add an uncertain amount of spirits of salts to his pailful of cleaning water. This produced an inflammatory reaction extending from the backs of his fingers up both forearms half-way to the elbows. The palms and nails were unaffected. About the wrists the skin was red, thickened, excoriated, and scabbed, but as one looked critically farther up the rash resolved into discrete red papules either with an excoriated

surface or with a small adherent whitish scale. Here, as is almost the rule in occupational dermatitis, a rapid cure followed rest from work and the application of calamine.

The skins of the young seem particularly sensitive to continuous immersion in water.

Emma M., aged 19, had worked for two and a half months near the hospital washing out jam jars in hot weak soda water. When seen on March 30th, 1920, there were large turbid bullae on the backs of her little fingers and chains of small blisters, some broken, some excoriated and septic, along the contact edges of her other fingers; there was no adenitis and no perionychia in this case.

Among elderly women many find constant employment as scrubbers, and a few develop an eczematous condition of their forearms and backs of the hands and fingers; the skin is reddened and thickened, it shows many erosions and fissures over sites of flexion, but higher up discrete follicles are discoverable. I mention this type of case to sound a warning against their re-employment at this work once their skin has become vulnerable. A well-established eczema of the hand, renewed by an immersion into hot soda water, may put the worker on the sick list for an intolerable period of time; a short dose of x rays is the best means of hastening a cure in indolent cases of this character.

It was in a professional scrubber, Sarah W., aged 48, that I saw at the base of the left palm a prominent oval bursa covered by a thick broad callosity; occupational bursae are not common, and this, though out of place, may perhaps be recorded here.

Two dental mechanics have come under my notice: both had lesions similar in appearance and distribution to many other cases of "professional" dermatitis; both showed thickening, redness, fissuring, and scabs on the backs of the hands, knuckles, and fingers of both hands, Mr. A. B. having perionychia of the nail of the left index finger; yet, considered together, they illustrated what appears to be a maximum in industrial dermatitis—namely, that skin reactions may be constant to varied irritants. Jessie W., aged 30, handled plaster-of-Paris, rubber, benzene, and "green acids" for cleaning metal plates; whilst A. B., aged 34, handled plaster, rubber, hydrochloric and nitric acids; both may have been reactions to an acid irritant, but benzene is not innocuous, as is shown by the case of Kitty R., aged 19, who had been a golf-ball painter for over six months and who cleaned her hands after work in the naphtha used as a paint solvent; on the backs of both her hands and fingers were circular areas made up of aggregated small red follicular papules with abraded surfaces and small adherent scabs. It took from October 4th, 1919, to December 22nd of that year before these lesions were well, although she was kept from work and the hands were dressed daily with zinc carbonate and lanoline ointment. Naphtha and phosphorus (Fig. 6) appear to give rise to very chronic resistant affections.

The Food Industry.

The food industries that have come before us as cases of dermatitis have been singularly few. Barley, peas, figs, flour, and sugar have been the only agents brought to my notice.

T. S., aged 49, was a case of barley itch. He had been engaged in unloading a cargo of barley from Morocco and had had an itching eruption for about two days; others of his mates were, he said, similarly affected. On both his arms and on the outer sides of his thorax was a heavy outbreak of close-set, large red papules, many unbroken, many with scabbed or bleeding apices. The whole eruption cleared away quickly on the application of 2 per cent. naphthol ointment, but when, three days later, he brought us a sample of the grain no parasites could be obtained.

June is the season of pea picking, and a Romford resident, aged 51 came to Dr. Sequeira's clinic on June 30th, 1921, with extraordinarily large bullae on her left elbow and both wrists, due to the irritating effects of the May weed. Although this affliction is known in certain localities, and the irritant effects of this plant are known to botanists, yet so unique was it in our experience that Dr. Sequeira published a full and illustrated clinical note in the *Lancet* of September 10th, 1921.

The *Carpoglyphus passalarum*, or "sculptor of figs," is not recognized as a parasite of dermatophilic tendencies, and S. S., aged 24, is possibly the only case of this on record. This was a sturdy workman employed in shovelling up a store of figs that were to be made into jam for domestic use. Of twelve workers on this job eight were similarly affected. On June 17th, 1920, on the forearms, backs of the hands; and on his face, were close-set reddish and pink itching papules of small size; they had been present for six days. S. S. kindly brought for us a sample of the figs, which were small and

apparently dusted over with a fine brownish deposit, which on close inspection appeared endowed with movement. Microscopic examination of this dust revealed the fact that it consisted of a countless horde of parasites, many alive, many dead, and many in fragments; larval, pupal, and adult forms could be seen. It is some comfort to reflect that jam, even from cheap tins, is made by a sterilizing process.

My friend Dr. Ingor Willey, who is the medical officer to a very large baking firm, tells me that he has seen many cases of bakers' itch, yet I have seen only one example of this affection; it may be that the condition responds well to simple treatment, and these cases do not reach hospital, for certainly bakeries are numerous throughout the East End and their washing facilities are but moderate. Individual susceptibility appears to play a great part, for my only patient suffering from bakers' itch had two previous attacks, one before and one since the war, and now showed an erythematous condition, of four days' duration, on both his hands, wrists, and forearms, with numerous follicular pustules of the epidermis, which, however, rapidly subsided with repeated fomentations. This man had always worked in a hand bakery, and handled only flour, yeast, and salt, and no preservatives. He was of clean habits, and careful examination in bed revealed no other septic foci. He was very nervous, with glib knee-jerks and tremulous, sweating hands.

Sweets and sweet biscuits are manufactured near the hospital, and there are big sugar refineries close by. The only case of "sugar itch" I have seen was as follows:

A sugar warehouseman, J. P., aged 37, when first seen on May 13th, 1922, had an acutely red inflamed condition of both hands, fingers, and wrists; over the backs of his wrists were numerous linear breaches of the surface, and between the fingers the skin was sour and sodden. By May 25th this eruption had spread to the face and neck, but at the end of another week he was able to cease treatment.

Preservatives and Antiseptics.

The following case was indubitably due to a too zealous use of a stock disinfectant, which indeed the boy admitted:

A boy, aged 15½, had been employed as a barber's assistant for one week, and had been thoroughly lectured as to the necessity for the use of antiseptics. His hands were a bright pink colour, they sweated freely, and were covered on the posterior surface of both hands and fingers with innumerable close-set small clear vesicles; on the palmar aspect of the fingers the vesicles were fewer, and in the palms of the hands were only a few widely separated sago-grain-like nodules. The eruption subsided rapidly on the application of calamine liniment.

Paper that is to be sent abroad is almost invariably passed by a machine through a solution of formalin in water and glycerin; a 4 per cent. formalin solution is usually used. In January of last year my attention was called to a little outbreak at one factory employed in making such paper.

Mary S., aged 23, had been at this work for two years, and says that she has had a rash on and off ever since she was so employed. She alternates on this employment, one week on and two weeks off, but during the off time wraps the finished rolls in paper and so is still exposed to formalin, though to a less degree. There was a coarsely papular rash with apical scabs profuse on both wrists behind, together with bad perionychia of the right middle finger and a little about the thumb and middle fingers of the left hand. Ethel C., aged 21, had also tended this process for two years, and alternated, as did all the girls employed on this particular work. There were numerous fissures in reddened skin over the joints of her fingers and thumbs, with a very little reddening about the bed of the right thumb nail. There was much redness, fissuring, scaling, and slight scalding between all her fingers. When seen at the factory her sister showed a milder similar state, and three other girls showed mild cutaneous reactions to their employment—that is, cracking of the skin, soreness of the backs of the hands, or cracks beside the nails.

The inveteracy of formalin dermatitis, and the extraordinary sensitiveness of the skin to this agent once a reaction has been established, is well known by experience in their own person to all histologists. The most careful attention and cleansing of the skin, the application of emollients, the early abstention from all contact when the skin is affected, is a method of relief that should be urged by all doctors who meet with such cases in their industrial practice. At the factory, girls with moist soft palms seemed to experience no trouble, whereas Ethel C., the worst affected, had had a dry ichthyotic harshness of her palms and soles from birth. Ethel C., removed from work

and given calamine liniment and a zinc ointment, was well in a month.

G. C. described himself as a "chemical worker," but on further interrogation said that it was his duty to make and fill barrels with a solution of SO_2 in water for sale to fruit preservers. He showed on both his forearms, on the backs of his hands, and to a much less extent on his face and neck, very irritable close-set pink follicular papules of varying size with a little cracking and soreness of the large folds of the palmar skin. His hands were sweating very freely, a point of clinical moment in similar cases arising in dyo workers and in the explosives industry.

Oil Dermatitis.

I would preface my remarks on oil rashes by short notes on three recent cases I have seen.

1. G. B., aged 32, is a die and staple maker. His lesions had only troubled him for two days. Both his forearms showed numerous but discrete red papules, many of which have black plugs in their centres.

2. C. O., aged 38, was a skilled tool-setter. He showed several discrete indolent boils on both his forearms of three months' duration; this (May 25th, 1922) was his third attack; previous similar attacks had dated fifteen and eight years previously.

3. L. T., aged 24, was a motor fitter. He came to the hospital first in July, 1920, with boils on his forearms, and the occupational factor was overlooked. He relapsed and came again in November, 1921, with large indolent follicular pustules on both his forearms and extending a little way up his arms. There was slight æne of the face without pustulation.

The distinctions between soluble oils, cutting compounds, cutting emulsions, and cutting oils are technical and need not detain us—they are fully set out in a memorandum of the Department of Scientific and Industrial Research in 1918—save that in the "cutting compounds" free alkali up to 2 per cent. of caustic soda may be present. These substances are used by the hundred gallons in engineering workshops for cooling, lubricating, and cleansing purposes. A report by my assistant, Dr. J. B. G. Skelton, will show how essential it is to have an insight into actual factory conditions in order to come to any opinion whatever as to the causative factors in oil dermatitis—uncleanliness, mechanical injury, and the oil itself all being intertwined. I would like particularly to call attention to the washing arrangements.

"I visited this factory on account of a report from the manager that cases of dermatitis were occurring there. The first two cases that I saw were typical scabies, and the next was a typical impetigo contagiosa. All the other cases consisted of a diffuse erythema over the backs of the hands, between the fingers, and on the under surface of the forearms and elbows. All these cases were occurring in girls cleaning shells with a turpentine substitute, and a diagnosis of oil rash had been made. The girls complained of much irritation and itching of the hands and between the fingers. On examination there was a diffuse reddening of the skin over the backs of the hands and between the fingers, and in some cases along the under surface of the forearms and elbows. The hands and arms of the workers were covered with the dirty oil, and in this oil was embedded a large number of very fine steel filings, easily seen with a lens, and which had been washed from the shells during the process of cleaning with the turpentine substitute. The hands, arms, and in some cases the legs of these workers were covered with oil, and a few had marked dryness of the skin over these areas. The turpentine substitute used contains spirit, but no exact analysis was obtainable.

"I think that there are two factors in the production of these cases: (1) a dryness of the skin due to the spirit in the turpentine substitute, and (2) the irritation and minute abrasions caused by the steel filings which are held on the skin by it. The erythema around the elbows and forearms is accounted for by the girls leaning while at work and thus rubbing in the fine steel particles.

"I saw one case where the skin of both palms and the backs of the hands had desquamated, preceded, so I was told, by the original irritation and redness. At this factory 850 workers are employed. The medical arrangements are looked after by a local doctor, who goes to the factory when required. No preliminary examination is made, and records of cases are kept in book form. The welfare and nursing arrangements are looked after by Miss D., who has under her three nurses.

"In attempting to deal with these cases the washing arrangements are of first importance. There are 21 washbasins in the factory, and roller towels, which were extremely dirty and oily; also there is no soap kept in these washhouses. Tins of antiseptic soap are given to the workers, who are expected to bring them daily. I was told by the welfare supervisor that a very large proportion of the girls do not bring this soap, so that the washing, in a large number of cases, consists of holding the hands under a stream of water and then wiping them on the roller towels. In addition there are three

baths, originally built for the foundry men, but which can be used by the girls on special days during the week. I was told that these were well patronized."

Of another engineering factory I have a note:

The cases I saw were of one type—namely, follicular impetigo affecting the hair follicles over the hands and forearms and in some cases the legs. The arms and hands of these workers were coated with oil and in this oil were embedded large numbers of steel particles (July, 1917). The oil used is very dirty and is only changed about every two weeks. For 360 girls 10 washbasins and 6 very dirty roller towels are supplied. There is no washing accommodation for the men and boys; some of the latter aged 16 work ten hours a day and cannot wash through this period. As the factory conditions seem to me so important in the consideration of oil dermatitis, may I add a third note I made at still another engineering factory?

I visited this factory on Wednesday, September 19th, 1917, to investigate a complaint of poisoned arms among men working on greased wire ropes. The trouble complained of originated in a room about 25 by 10 yards, in which are four (there will be eight) wire-winding units. These units consist of a drum holding a supply of twisted iron wire, which is passed through a box full of a mixture of oil and graphite and then wound on a second drum. Two men are usually at work on each unit hammering and pushing the wire into good alignment and working the various levers. Twenty-five men all told work in this room, and their hands and arms are all covered with this oily composition. Their clothing is protected by boiler suits and mackintosh aprons. There is no washing accommodation for these men. I examined two men at work.

(1) William D., aged 21, had a whitlow on the left forefinger of a week's duration. (2) Frank S., aged 35, had an indolent boil 2 cm. across on his right wrist. Both these cases were badly dressed with soiled rags; metallic particles could be seen in amongst the grease on their forearms and hands. The wire arrives more or less greased from various sources.

It is difficult to find words strong enough to express the lamentable state of the washing and lavatory accommodation for men here. That for the women has been well designed, is conveniently situated, and is sufficient. It consists of a special building with trough and basin facilities for forty workers, under the special charge of one woman, and in addition in the shell-case-making department is a room where five tin basins are supplied on a leaden shelf; but for the 200 and more men employed at this factory a bucket of water is brought up to the wire-rope-winding room, and one basin is provided in the watercloset shed. There is a row of six waterclosets, two only with doors, that suffice for the working staff of this factory. They are situated in a dark lean-to with a muddy earthen floor. For the male office staff and 18 inspectors one watercloset suffices.

In another factory (A.T.) there were in one year twenty-six cases at least of oil dermatitis, three of which developed cellulitis. An irritating erythema, follicular pustulation, acne, and multiple symmetrically distributed indolent boils may result from work involving continuous exposure to oil. It is remarkable, however, in children how few rubbings with camphorated oil will produce grouped comedones with pustulations on the chest, and I have seen an elderly gentleman whose head was covered by large close-set comedones, due to the application for seven years, morning and night, of a pomado he had sent over to him specially from Nice to London.

Dr. McLachlan, in a paper in the *Glasgow Medical Journal* of April, 1922, draws attention on page 217 to the ease with which these cases may be missed; up and down the country they must be overlooked in scores to-day. If work is suspended these cases get well quickly, otherwise it is the experience of many that they are most rebellious to treatment. Dr. McLachlan stresses, and I most emphatically agree, that "the workers' habits are themselves a danger."

Occupational Tinea.

Of these I have seen but two noteworthy cases.

R. S., a labourer aged 47, works at the Victoria Docks unloading hides, and he was sent to the London Hospital by a local practitioner as a case of anthrax. His lesion has existed for fourteen days and when seen was a ringed reddish eruption about 1½ inches in diameter over the base of the left thumb. It was a definite case of tinea circinata—the fungus was found in scrapings.

The case of C. M., aged 36, is a little more startling, however, for he is a barber in the active practice of his art, and he is known to us to have had tinea of his finger-nails since at least 1915. Three nails are affected on his right hand, and only since suppurating onychia has developed have we been able to remove even his right thumb nail.

Some barbers are greatly troubled by stiff short hairs working under their nails, and find that if these hairs are not

pulled out daily with tweezers suppuration quickly follows. On mentioning this to a large farmer recently, he took to see a labourer who cuts up haystacks and stacks of straw and in so doing frequently drives fragments under his nail lacerates the nail margin. To obviate this he wears lead thimbles when he thrusts his hand through the stacks.

Tar.

"Epitheliomatous ulceration due to tar and pitch, bitum mineral oil of paraffin, or any compound, product, or resi of any of these substances" was made compulsorily notified to the Home Office in November, 1919. The tar industry, essentially a healthy one, and a far larger proportion of gasbeards are found in this industry than in any other I know. I have seen tar cancer develop in the following occupations:

Pickling telegraph poles.	Chemical factory labourer.
Tar distilling.	Gasworks labourer.
Pickling sleepers in creosote.	Pitch bed breaker.
Gasworks stoking.	Barge loader.
Anthracene labourer.	Road sprayer.

I have reviewed all the cases that have occurred at London Hospital since 1903 to August, 1920. The parallel between tar carcinoma and x-ray carcinoma is close and striking. In both, years of occupational exposure are the rule, in both the end is a squamous-celled carcinoma, and both may show, singly or combined, pigmentation of the skin, multiple telangiectases, small keratoses, warts, and of multiple cancerous lesions.

All tar and pitch workers complain of irritation of the skin on washing, and owing to this the older worker in the trade is generally a rather dirty fellow; some men will apply whitewash to their face as a protection before commencing the day's work. The tar warts, histologically, are also carcinomatous; warts the size of a pea show epithelial downgrowths with cell nests; yet for years they show a benign character, having a natural tendency to fall off, leave white, clean, pit-like scars. It is the habit of many workers to carry about a lump of soda and spit on it and rub it on the warts—when they remember them. Ten to forty years' employment in tar are needed to bring on these epitheliomatous changes, and warts may precede the appearance of any obvious carcinomatous ulcer by anything from two to twenty years. The ages of men affected with tar cancer vary: my collection from 33 to 75 years of age, and a feature of interest which I cannot attempt to explain is the late onset that these cases may show. I can best illustrate this by example. T. L., aged 68, had been a railway booking-office clerk for twenty-eight years past; for twenty-eight years before this he had been employed as a gasworks labourer for the last two years he had a wart on the left side of the scrotum, which grew slowly and was excised as a carcinoma ulcer in 1908. Bland-Sutton (*Tumours Innocent and Malignant*, p. 215) mentions a case of soot cancer with a similar clear latent period of thirty-five years.

In order of frequency the sites on which these lesions first appear were face, scrotum, and forearm, and all sites may be affected in the same patient. I have said that these lesions are of a very low grade of malignancy; in a paper on this subject in the *British Journal of Dermatology* in 1920 I stated (p. 1) that in no case had secondary deposits been found in the regional lymphatic glands removed at operation. This year, however, in a case of tar epithelioma of the scrotum, the lymphatic glands were enlarged in both groins, and after the removal of the primary growth continued to enlarge, and ulcerated through the skin and has every appearance of secondary carcinoma. These tar carcinomata respond extraordinarily well to radium; a growth the size of a shilling will generally disappear after a single sitting of two hours exposure, though it is advisable to repeat this in six weeks time. In all respects, save multiplicity of cancerous lesions, anthracene workers carry the same liability and the same favourable prognosis as workers in tar and pitch; tar workers need supervision in order that their lesions may be treated in their early stages; to secure this result a frequent short visit by a practitioner to every tar factory would ensure that no cases were allowed to run on and become incurable. Tar cancer, as far as present knowledge goes, is not preventable but should not kill.

Dyes.

Of dye dermatitis we see far too many cases. Mostly they occur in young workers, the ages of our last six cases being 28, 18, 19, 20, 24, and 40 years of age. They are fur sewers, fur dyers, or fur dealers. The causal agent is suggested at once by a glistening deep brown staining of their nails and of the pads of their fingers; sometimes the whole hand is brown in colour. Generally their palms are moist and show free perspiration; the lesions produced vary from a general erythema with raised red follicular papules to a gross pompholyx eruption on the palms and fingers with concomitant fissures, impetiginized erosions of the cuticle, and acute perionychia. Subjective symptoms are slight, and if the patient will refrain from work a rapid recovery on simple treatment is the rule. It is not uncommon when the hand lesions are in an acute phase to see an eruption on the face and neck in the form of sheets of scaling erythema. It is difficult to account for the onset of these symptoms except by supposing that after repeated assaults the threshold of tolerance of the cuticle becomes lowered, for many of these workers have been in the industry for from three years upwards. The source of the dye may vary, but never is a whole workroom laid out at any one time.

Susceptibility.

In establishing any new industry having its own health hazard a largely immune body of workers can be secured by eliminating persistently at the first onset of symptoms every worker showing signs of intolerance. A. H., an unskilled labourer aged 32, was employed by a local foreign employer in a small way of business for a week on staining wood with potassium bichromate; the next week he came to us with the stained, ulcerated, and inflamed condition of his hand as shown in the photograph (Figs. 2 and 3). He said that in the last three months twelve men had been sacked by his master for the same misfortune. This sounds ruthless, but, if this stain is to be used, those with susceptible skins must be eliminated, and men who by skill, cleanliness, and extra tolerance can stand this work will stay by this industry. On a large scale this experiment has been worked out in the manufacture of tetryl at Waltham Cross, near London, and at Queensferry, near Chester. At Waltham Cross factory tetryl, a high explosive, had been manufactured for years before the war and had acquired a set of immune skilful workers. Queensferry was started during the war with unskilled labour; its preventive welfare and medical care reached a very high standard indeed, yet the incidence of tetryl dermatitis was appallingly heavy so as to lead to grave difficulties in the obtaining of labour and in appeasing the workers with "danger money" that satisfied their appreciation of the risk to health and limb that they were running. Every new industry has at first a heavy industrial casualty list.

A skilful worker can do a piece of work in much less time and with less distribution of noxious material on himself and on his surroundings than a newcomer to a job; hence it is that adequate instruction in correct methods of work is in itself a great preventive measure against industrial ill health of many kinds. Complete protection is assured when by inventive genius and engineering skill all hand contact is eliminated.

I have collected these cases from many sources, and I owe more than I can express adequately to the assistance and consideration of Dr. J. H. Sequeira.

The chief lesson that I would like to press home is the ever-present need of being alert for an industrial origin in cases of dermatitis of the hands and face; and secondly, that there is little or no specificity in the skin reactions—erythema, pustulation, perionychia, powder holes, and carcinomata may each be due to varied industrial causes, and until the etiological aspect of every case is adequately realized curative and preventive medicine are alike impotent.

DISCUSSION.

Dr. T. M. LEGGE (Chief Medical Inspector, Home Office) said he had been helped by a classification (for which he did not claim any originality) of the causes of industrial dermatitis as due to (1) certain chemical substances like potassium bichromate, arsenious acid, and certain finished dyes; (2) substances which soften and macerate the skin, such as alkalis; (3) substances which dissolve and remove the natural grease from the skin, like turpentine, petroleum, benzene, benzene

and its homologues, and their nitro and amido derivatives; and (4) processes which mechanically injured the continuity of the skin, such as brushing, scratching, and rubbing. In the prevention of these on factory premises much more medical supervision was desirable to prevent secondary infection. With the substances which dissolved the natural fat from the skin he believed in the attempt to restore, as far as possible, the natural lubricant, by the use of an ointment of equal parts of lanoline and castor oil after the work of the day had ceased; and in dermatitis due to unavoidable dust in the air, by the use of powders rather than ointments while at work, so as to introduce a mechanical obstacle against the alighting of the injurious dust. He referred to the specific effect of pitch, tar, and paraffin in setting up irritation of the skin which eventually might become malignant, and to the absence of such effect in the manufacture of bichromates and their use in dyeing and tanning, which also set up intractable ulceration, but showed no tendency at all to malignancy.

Dr. NORMAN WALKER (Edinburgh) said that he had long been interested in occupational dermatitis. It had always been his practice to inculcate on all students the necessity of ascertaining the exact occupation and work of all patients complaining of "eczema." He desired to say how much we had gained by intelligent co-operation with the Home Office. Intelligent co-operation between the workmen and the doctor was also highly desirable, and in certain instances had been very successful in avoiding and preventing the dangers associated with the paraffin industry. In other cases where that co-operation had been lacking these dangers had been much more real and had led to serious disasters. He had also been much impressed by the idiosyncrasies of the skins of different patients, some of whom were sensitive to one thing and some to another. He considered this idiosyncrasy a factor of great importance, and he believed that any idiosyncrasy once developed remained permanent for the individual affected. The best fat or grease for use in preventive treatment was also a matter of idiosyncrasy—some did best with lanoline, others with olive oil.

Dr. FREDERICK GARDINER (Edinburgh) had also been interested in this subject for a number of years. He had found that of all the cases of dermatitis seen by him at least 66 per cent. were cases of occupational dermatitis, but in 14 per cent. the dermatitis was preceded by a definite illness, and 63 per cent. showed a preceding abnormality of the skin—for example, seborrhoea, hyperidrosis, or psoriasis—which no doubt made it more sensitive to the action of the irritant. He had found that slight alterations in the materials used would often cause an outbreak in a workman who had used with impunity for years a formula not very different from the one newly introduced. He had found that there were two types of case: one where the workman became affected as soon as he entered the works, the other where he became affected only after he had been engaged in his occupation for many years.

Dr. G. H. LANCASHIRE (Manchester) said that the possible sources of irritation were legion. He merely desired to mention certain out-of-the-way substances which had come to his notice. One of these was novocain, which he had found to cause dermatitis in a dentist. He did not know of another case of the kind in this country, but it had been previously described in America. He had also seen two cases of "Insecto" dermatitis in barbers. Although it was common enough among women or men who dyed their hair, these were the first cases he had known among barbers.

Dr. KENNETH WILLS (Bristol) said that he had had exceptional opportunities of observing linseed oil dermatitis, because the Bristol Infirmary was next door to a linseed oil factory. It was a not uncommon idiosyncrasy. He quoted a remark by Dr. Palmer that it was marvellous how dirty people avoided skin disease; he felt sure that anything tending to dry the skin and make it crack made it more liable to dermatitis; hence he deprecated too much washing. He was interested in the case of barley itch described by Dr. O'Donovan because he had himself met with a small epidemic of barley itch among men employed in unloading a cargo of barley. He had found that it was due to the barbs of a certain weed which had got mixed up with the barley. One other interesting and unique case he had noticed—that of a man whose hands were sensitive to hemp.

The PRESIDENT (Dr. Loslio Roberts, Liverpool) said that many important points had been mentioned by the previous speakers, and he hoped that they would be able to draw some general conclusions from the discussion. For himself, he was of opinion that there was no such thing as a local disease, although there might be a disease confined to a small area. The cause of these eruptions he regarded as twofold: (1) A defect in the external defence—in other words, a defect in the keratin membrane of the skin, which therefore ceased to be a complete protective organ. (In this connexion he desired to emphasize the importance of examining the whole surface of the skin in any patient suffering from dermatitis.) (2) The personal idiosyncrasy of the patient, which he considered chemical. The introduction of foreign proteins into the body from various septic foci was an interference with the chemistry of the skin and reduced its resistance. Also foreign carbohydrates of the di- and poly-saccharide types, ingested with the food, might, since they did not enter into the normal sugar metabolism, sensitize the skin to certain irritants. Hence he thought that the question of diet might form an important part of the preventive treatment of dermatitis. He did not agree with the use of ointments as advocated by Dr. Legge.

DERMATITIS ARTEFACTA.

BY

GEORGE H. LANCASHIRE, M.D., M.R.C.S.,

Honorary Physician, Manchester and Salford Hospital for Diseases of the Skin.

A RECENT survey of the literature on this subject leads me to think there may be points still worthy of discussion. Moreover, a more complete type classification may be attempted, and a clearer line of treatment indicated.

In this brief paper I shall exclude the ordinary forms of malingering practised for a definite and reasonable object—evasion of army service and the like—and also cases, of which we have all seen instances, where a man or woman seeks to defraud the Workmen's Compensation Act. As a subdivision of this class may be placed those, of whom I have seen several examples, who artificially stimulate a genuine eruption so as to prolong their stay in hospital. These acts are sane, if immoral, but in the dermatitis artefacta we are considering the bulk of the subjects are approaching or have reached the border-line of insanity.

A fair proportion of the subjects are hysterical, and may show the usual stigmata of that condition, but a number of cases that I have seen have not been of the hysterical or even neurotic type. They have not had the facies or manner suggesting any departure from the normal, and some have even discussed their skin lesions with an engaging frankness that was no doubt meant to be most disarming. On the other hand, the subject may have a sullen expression, with furtive and hang-dog manner when interviewed. The point I wish to make is that manner and expression in these people are not to be relied on for diagnostic purposes in the same way that one relies upon them in other psychopathic conditions.

In a number of cases, as is well known, the suggestion of self-mutilation has come to the patient in the first instance during a genuine attack of skin disease, which has furnished lesions to be copied. No doubt a higher percentage of these cases would be noted could they be seen or traced from the beginning.

I would suggest, as a psychological attempt, the following classification of cases:

Class 1.—Composed in the main of hysterical subjects who mutilate themselves with the definite object of exciting pity and gaining notoriety of sorts. This class comprises individuals who are prepared to go to the utmost limits of their endurance in order to keep up appearances, and some of the worst examples of self-mutilation belong to it. The most extreme case on record is described in *La Presse médicale*, June 10th, 1908:

It is that of a man of 30 who produces black gangrenous patches on his arm by the use of caustic potash. He consults fifteen doctors in turn, and preserves their names and diagnoses, which include trophic skin trouble, neuritis, myelitis, hysteria, syphilis, *gangrene*, and so on. He has various treatments of the brachial plexus, and finally the limb. The remaining arm subse-

quent about this time he arrives at Proere the real condition is recognized. an on sound lines and he is cured.

I believe that with proper handling the prognosis in cases of this class is good.

Class 2 includes a more irrational type, where the motive is indeed hard to find. These people would appear to suffer only to please themselves, and to find a morbid satisfaction in contemplating their own infirmities. They make no effort to secure the pity of others, and are content to play to an empty house. Some of them come definitely within the province of the alienist, and in most cases the prognosis is bad.

Class 3.—In this class motive again would appear to be entirely absent. The patient is not anxious to pose as an invalid, but on the contrary would generally appear ashamed and distressed by the appearance of lesions. There is an entire absence of the self-satisfaction shown usually in Class 1. These cases, of which I have seen several examples, appear to be examples of obsession and sudden uncontrollable impulse. I will briefly quote one instance.

A young lady was brought to me a few years ago by her parents. Her face and neck were much disfigured by oval-shaped excoriations and crusts, all in the same stage of evolution and obviously suggesting factitious dermatitis. The young lady was a professional musician, a hard worker, and anxious for success. I learned that she had had repeated attacks of the eruption, and that these happened always on the day she was billed to appear at a concert. In a private interview she confessed to me that some uncontrollable impulse made her mutilate herself in this way on the very day that would prove most disastrous for her.

There would appear to be in this type of case something akin to the impulse which drives certain people to jump from a precipice. I find, too, that the victim is relieved when the secret is shared by the doctor, and that subsequently the cases have done very well.

Class 4.—This class has not, I believe, received attention before. I will illustrate it by a recent example.

A young lady, a governess in a private family, was sent to me by her medical man suffering from an eruption on the face and neck, which it was feared might be contagious. The lesions—oval and linear excoriations—appeared to be self-inflicted, and I learned that they were produced by rubbing the skin. I may add that the patient herself appeared quite relieved when she was able to make the confession, for which she had never been asked before. She told me that the rubbing was a pure "habit" and not done with any wrong motive—indeed, she would be very glad to be cured of the practice. After full inquiry I came to the conclusion that this was indeed a simple case of a habit to be placed in the same category as nail-biting.

Diagnosis.

The diagnosis of dermatitis artefacta may be easy or otherwise, according to the skill which the patient has used. People of a low order of intelligence commonly manipulate in the clumsiest fashion, and there is no difficulty in recognizing the hand-made article when one sees a fresh lesion from which a gravity-made streak of corrosive fluid is depending. On the other hand, one sees artefacts which are extremely difficult to certify, and there may be about them merely an undefinable something which rouses one's suspicion. These are, of course, cases which must be carefully watched—perhaps with the skin under a protective covering—before a pronouncement can be made. The main points of diagnosis include the history of the patient and the case, the distribution, shape, and character of the lesions, and especially their uniformity. Suggestion to the patient of a new site for the next eruption is also a useful guide.

Although one sees cases in which chemical irritants and corrosives have been used—acids, alkalis, and so on—in some cases the mildest irritant seems to suffice. I have seen eau-de-Cologne produce alarming lesions in one lady, and this probably points to a predisposition, psychic in origin, on the part of the skin. Many cases are the result of simple rubbing, as we know, and it is probable that the same amount of friction in a normal skin, with a normal mind behind it, would give negative results. To pursue the same line of thought, one is reminded of the Nancy experiments where under hypnosis suggestion alone produced eruptions. In fact the whole question is one perhaps more for the psychologist than the dermatologist when once the latter has pronounced his diagnosis. I have referred it to Professor Pear, the distinguished psychologist at Manchester University, who, while much interested in the subject, reports that as yet it does not happen to coincide with the lines along which he has accumulated any special knowledge. He writes:

"From a psychological point of view the interest is, of course, in the nature of the motive, or combination of motives, which bring about the production of such an unpleasant experience. It seems to me quite certain that the motive is of a nature more

complex and probably different in quality from those which actuate an ordinary person. It is quite probable that the whole problem is susceptible of illumination by psycho-analytical methods, and it would be extremely interesting if a dermatologist and a psycho-analyst could co-operate in a case of this kind. Beyond mentioning this I am afraid I have nothing of value to contribute to a subject which interests me very much indeed; except, of course, the reflection that the eternally recurring problem of the line between functional and organic is raised again in a very challenging form."

Pernct, at the annual meeting of the American Dermatological Association in 1909, suggested that in some cases of dermatitis artefacta there might be a "dual personality," the patient in his normal state being unaware of his delinquencies. I do not know how far this suggestion may be considered fantastic, but quite recently I saw a lady whom I had attended twenty years ago for this condition, and who still bears many disfiguring scars as a memento. She told me that she had not the slightest recollection of ever mutilating herself, though at the time she used a powerful caustic, producing deep and painful ulcers. I give you her statement for what it is worth.

It is unnecessary to labour the importance of being sure of one's diagnosis. At the meeting of the American Dermatological Association (1909) already referred to, Dühring commented on the few cases he had seen, but recalled cases which had been wrongfully labelled as dermatitis artefacta. My own impression is that probably more cases are overlooked than recognized. As would be expected, more examples turn up in private than in hospital practice, since the condition is more apt to accompany an aimless and idle life in pampered individuals.

Treatment.

As regards treatment I find no unanimity of opinion here. Ormsby (*Journal of the American Medical Association*, November 6th, 1915) does not advise confronting the patient with the charge, but telling her that there is no question whatever of the cause and instructing her as to dressings, etc. In lieu of expert treatment by the psycho-analyst, of which I have no experience, it appears to me that the only common-sense and honest procedure is to tell the patient, in private, that he or she is found out. I believe a *laissez faire* attitude, which, of course, is an easy one, is far too commonly practised. Nevins Hyde said he had always failed to secure a confession from the patient. That has not been my experience; indeed, in some cases relief has been expressed that the secret has been discovered. It would certainly be wrong to publish one's knowledge to the patient's family and friends, and such a course has been known to lead to suicide. But a pact may be made between doctor and patient which should offer success. At times a threat is justifiable—that should the evil practice not cease the parents or others would be informed; this I have seen effective. In this by-way of dermatology there is the greatest call on the doctor's tact and psychological powers, though, as we are all aware, these attributes are by no means needful only in the case of dermatitis artefacta.

ALOPECIA AREATA AND STRABISMUS:

A FAMILY GROUP OF CASES.

BY

J. GOODWIN TOMKINSON, M.D.,

Professor of Diseases of the Skin, Anderson College of Medicine, Glasgow;
Dispensary Physician for Diseases of the Skin and Physician to
Skin Electrical Department, Western Infirmary, Glasgow.

A SERIES of cases of alopecia areata occurring in one family has come under my notice during the last few years, presenting points of interest which appear to justify my making this contribution to the proceedings of the Section of Dermatology.

The family, the majority of whom reside some twelve miles or so from Glasgow, consists of eleven members—father, mother, and nine children. I have seen seven of them. Of the remaining four, two children, both adults, are inaccessible, having emigrated to Canada; the father and one son have not yet responded to my invitation to appear for examination. The following is a very brief history of those members whom I have seen.

Case 1.—Mrs. A., aged 49 years, states that she has suffered from "billion headaches" all her life. At about 9 years of age a bald patch appeared in the occipital region, as nearly as she can remember, and extended to the whole of the scalp. She remained

bald until 15 years of age. The hair then grew again spontaneously. About five years ago a bald patch developed in the occipital region and in both parietal regions, which quickly cleared up under ordinary local medication. On April 30th, 1921, I have this note: "Hair is generally thin, especially over left parietal area. Eye and knee reflexes appear to be normal." Since the age of 40 she has suffered from intermittent increased frequency of micturition. In April, 1921, she was under treatment for "no feeling in hands and head."

Case 2.—Son, aged 19 years. At about 10 years of age a bald patch appeared in the upper occipital region, and extended to the whole of the scalp. He remained bald for four years. After prolonged treatment with the vacuum electrode the hair regrew, save on a small area in the occipital region, which still remained bald on June 21st, 1922.

Case 3.—Daughter, aged 17 years. At about 8 years of age a bald patch appeared in the upper occipital region. She lost almost all her hair for a year. Local medication and prolonged treatment with the vacuum electrode the hair regrew and remained for about four years, when two very small bald patches developed. On June 21st, 1922, she appeared to be cured.

Case 4.—Son, aged 13 years. He is a somnambulist, and talks in his sleep. At about 9½ years of age a bald patch appeared at the vertex and extended to the whole of the scalp. Ordinary medication and finally the vacuum electrode were applied. All the hair regrew, but on June 21st, 1922, there had been some relapse.

Case 5.—Son, aged 10 years. At about 9 years of age a bald patch developed at the vertex and several other bald patches followed. Ordinary medication and the vacuum electrode were applied. On June 21st, 1922, there was still some evidence of the disease.

Case 6.—Daughter, aged 29 years. Has never had bald patches. There is a small traumatic cicatrix in the right parietal region.

Case 7.—Son, aged 7 years. No history of bald patches, but when seen on June 21st, 1922, a small area in the right occipital region showed hair of lighter colour and possibly of weaker growth. I am informed by the family doctor that a bald patch subsequently developed.

It will be observed that the disease appeared, in the majority of the cases, in the occipital region. This, however, is based mainly on the mother's evidence, as is the incidence of the affection at from the age of 7 to 10 years.

Mrs. A. states that she has a married son, aged 21, whose hair is thin, but he has never had any bald patches; another son, aged 26 years, whose hair is thin, is in Canada; and a daughter, aged 23 years, who has a good head of hair, is also in Canada. Mr. A., aged 50 years, has never developed bald patches. The family doctor states that none of the family has been under treatment for tonsillar hypertrophy or for postnasal adenoids.

Hairs from the scalp in Cases 1, 3, 4, and 5 were microscopically examined by Dr. G. Haswell Wilson of the University Pathological Department, who also attempted to make cultures on Sabouraud's medium, but failed to discover anything microbic or mycotic by either of these procedures.

It was noticed that several of the patients squinted, and as many members of the family as could be induced to attend the Glasgow Eye Infirmary were examined by Dr. W. Hislop Manson, who kindly reported as follows:

1. Mrs. A., aged 49, strabismus convergens, right.
2. Daughter, aged 16, strabismus convergens, right.
3. Son, aged 13, strabismus convergens, alternating.
4. Son, aged 10, strabismus convergens, right.
5. Son, aged 19, strabismus convergens, left (occasional).
6. Daughter, aged 29, strabismus divergens, right, cum myopia.
7. Son, aged 7, no evident strabismus, but mother states he occasionally squints.

Note.—Nos. 1, 2, 3, 4, 5, 7 suffer or have suffered from alopecia areata. Nos. 1, 3, 5 were completely bald. No. 2 was almost bald.

The first five of these cases have been under treatment for alopecia areata. The sixth has never developed it. The seventh, when seen by me on June 21st, 1922, showed a light-coloured patch of possibly weaker hairs in the right occipital region. I am informed by the family doctor that this seventh case has since developed a bald patch, presumably on the light-coloured thin area just mentioned.

Mrs. A. states that of the remaining three children, one, a married son, squints a little and has thin hair, but no bald patches; another adult son has thin hair, but does not squint; the third, an adult daughter, has no squint and a good head of hair. The family doctor states that Mr. A. has no eye affection except presbyopia, for which he wears + glasses.

From these records it appears that eight of the family, including the mother—and this might indicate an hereditary factor—have shown a pathological condition of the hair, which in six assumed the form of alopecia areata. Seven of these eight persons are strabismic. Mrs. A. states that her last five children are very nervous. All of them developed

alopecia arcata. Mrs. A. also says that some of the children did not squint until after beginning to go to school.

Is there a causative factor in these cases common to the two conditions, strabismus and alopecia arcata? It might be advanced that their association is merely coincidental. If so, it is certainly coincidence on an unusually grand scale.

With respect to the microbic theory Dr. G. Haswell Wilson's negative findings are against it. Also, were this family scalp condition contagious and the mother the source of infection, one would have expected an incidence earlier than the age of 7 to 10 years in the affected children, and also that the remaining children and the husband would not have continued immune.

In discussing these cases with Dr. Hislop Manson, he agreed that the percentage of squinters in the family was large, and stated that the greater strain upon the nervous mechanism controlling convergence and accommodation, after beginning to go to school, might account in some degree for the development of squint where it was deferred until that time. One of the theories of squint is that the equilibrium between the powers of convergence and accommodation is disturbed. These powers are dependant upon innervation.

It will be recalled that there is a possible maternal hereditary influence operating, and also that Mrs. A. suffered at one time from "no feeling in the hands and head," as she described it; also that five of her children are very nervous, one being a somnambulist. All of these squint and have suffered from alopecia arcata. Possibly further investigation might elicit other neurotic symptoms.

With evidence such as this it would be difficult to exclude the hair affection from the picture produced by nerve disturbance. Indeed it is strongly in favour of its inclusion as resulting from involvement of the function of trophic nerves. There is possibly some physiognomical suggestion of congenital specific disease in the mother, but I am not aware of any faulty obstetrical history. I doubt if she would submit to a Wassermann test. What the ultimate cause common to these optical and cutaneous manifestations is, if such cause exist, I have as yet been unable to discover.

In conclusion, this group of cases appears to lend strong support to the important part played by the nervous system in the causation of at least some cases of alopecia arcata.

My heartiest thanks are due to Dr. G. Haswell Wilson, Dr. W. Hislop Manson, and Dr. John Potheringham for their very willing co-operation in making these investigations.

SECTION OF RADIOLOGY AND ELECTROLOGY.

LEONARD A. ROWDEN, M.B., C.M., President.

PRESIDENT'S INTRODUCTORY REMARKS.

Dr. Rowden, after welcoming the Section to Glasgow, from whose university he had himself graduated some thirty years ago, said that there was so much work of real importance before the Section that it would not be right for him to occupy the time with any opening address. There were, however, a few points which he would like to mention for the future consideration of the members. Radiology and electrology had made rapid strides during the past few years and were occupying an increasingly important place in medicine. There was now hardly a single disease in which they were not of service in diagnosis or treatment. There was an ever-increasing demand upon these departments. The question was how such a demand was to be met. Would it be met by private enterprise, or by public institutions such as the large infirmaries, or by some scheme under the national health insurance system? He must leave that for the consideration of others, but he foresaw the danger of the almost complete extinction of the radiologist as a private consultant. The initial cost of plant and the cost of its efficient working were becoming so great as to be beyond the purse of the private practitioner. Another point for consideration was the status of the radiologist and electrologist. He thought that radiologists and electrologists should only give their services to those who were referred to them by other practitioners. He believed that there was a much greater tendency for patients to be referred to the public institutions, more especially by the honorary staffs.

DISCUSSION ON THE X-RAY TREATMENT OF DEEP-SEATED CANCERS,

WITH SPECIAL REFERENCE TO ERLANGEN METHODS.

OPENING PAPERS.

I.—J. R. RIDDELL, F.R.F.P.S. GLAS., L.R.C.P., L.R.C.S. EDIN.,
Medical Electrologist, Western Infirmary, and Lecturer, the
University, Glasgow.

THE essential differences between the Erlangen method and the older one in x-ray therapy lie in the facts that the object in the newer system is to attain homogeneity in the rays used, to administer an equal dose to all the diseased tissues, and to do so at one sitting. The quantity given is predetermined, and is such that it will destroy the diseased but not the healthy tissues; they will be damaged to a greater or less degree according to their radio-sensibility, but the quantity must be short of that which will destroy them.

Homogeneity is attained (1) by using rays of very high penetration (short wave-length)—the equivalent to a 16-inch spark-gap between blunt points in air, and (2) by filtration. The thickness of the filter depends to some extent on the apparatus used. For a gas tube and coils 0.5 mm. of zinc is employed. With a Coolidge tube greater thickness is necessary.

Much research has been carried out by several investigators independently to determine just what doses will destroy the diseased cells in various conditions, and the conclusions to which they have come are approximately the same.

The measurement of the dose is regulated by time, which means that the apparatus must be run under standard conditions; any change in the conditions would naturally alter the output, and consequently the time necessary to deliver a certain quantity. The unit propounded by Seitz and Wintz is that quantity of radiation which will produce a slight redness after a week and leave a slight tanning on the skin after a month. This is called U.S.D., and is taken as 100 per cent. On this basis the doses that have been determined are:

	Per cent.
1. To produce the menopause (called the castration dose) ...	34
2. To destroy sarcoma (the sarcoma dose) ...	70
3. Tuberculosis dose ...	50
4. To destroy carcinoma (the carcinoma dose) ...	110
5. To damage seriously the bowel ...	135
6. To damage seriously muscle tissue ...	180

The problem is to give the full dose to all the diseased tissues, and it is not always possible to do so. It means that the radiologist must attempt to visualize the location of the disease to its extreme limits and include all this area in the dose.

The rays in passing inwards from the surface lose in volume as the distance from their source increases; also they lose by absorption in the tissues through which they pass; on the other hand, they gain to some extent by the secondary radiation which they set up in the tissues. Obviously this secondary radiation will be greater with a large port of entry than with a smaller one. It is thus evident that the estimation of the dose arriving at a given point below the surface is a very complicated one indeed. It is still further complicated by the fact that each tube has its own "percentage deep dose"—that is to say, that two tubes may, to all appearances, be exactly the same, yet it is found experimentally that they do not give the same percentage at a given point beneath the surface; for example, one may give 17 per cent. and the other 24 per cent. To give the full dose to a carcinoma with the former tube it would be necessary to find seven ports of entry (and this would probably be impossible); while with the latter five ports would be sufficient.

The percentage can be improved by increasing the "tube skin distance"; thus a tube giving 15 per cent. at a point 10 cm. deep from the surface when placed 23 cm. away from the skin would give 26.2 per cent. if it were placed 100 cm. away. If at the first distance the time taken to give the "unit skin dose" were thirty minutes, at the last it would be nine hours.

The difficulty in determining how many ports of entry to employ, and at what angle to direct the beam of rays, is great. For example, suppose one is treating a carcinoma of the uterus, and determines to use four ports of entry at 35 cm. "target skin distance," and that each beam gives 26.4 per

sent. at 10 cm. deep—namely, at the centre of the tumour—that point would receive 105.7 per cent., which may be sufficient. But if the two beams from the front are so directed that they overlap at a point 3 cm. beneath the surface, this more superficial point will receive 136.75 per cent.

Now, if bowel happens to be there (and it is quite conceivable that it might be in a thin person) there is every likelihood of damaging it seriously—possibly producing ulceration.

I think I have said enough to show that while there are difficulties arising from the apparatus, such as the standardizing and keeping constant of tubes, the chief difficulty is so to arrange the skin tube distance, the number and sizes of the ports of entry, and the exact direction of the beams, that all the diseased tissues receive the full dose of rays, while none of the healthy tissues receive too much.

In the Frankfort clinic an ingenious instrument, known as the "field selector," has been elaborated. I have not seen it, but I imagine it should be of great assistance in this connexion. It is described in the *American Journal of Roentgenology* (June, 1922, p. 343) in the following terms:

"To make possible a graphic study of each problem we have constructed in the Frankfort clinic a device which we have named a field selector. This consists of a box illuminated with electric bulbs from beneath. Over it is placed a translucent plate of glass upon which are printed certain figures which are used as signals. They are printed in one colour with the different symbols in percentages of strength of colour. A drawing upon a glass plate representing a cross-section of the body and showing the location of the growth is now placed over the illuminated plate on which the symbols are printed. We have prepared a series of celluloid dummies representing beams of x rays produced at different voltages and through different values of filters at different distances from the body and of different dimensions of field, on which are shown by decreasing intensity of colour, starting with one hundred at the surface, the percentage depth dose at varying depths. These are stained with the same colour as the symbols printed upon the plate, and when two or more of these dummies are visible or whether they are to cover the lesion, one through the superimposed

celluloid films. The triangles disappear when 30 or 40 per cent. of the standard skin dose is reached in the colour values of the dummies. The quadrangles disappear at 60 to 70 per cent. of the standard skin dose, and the points at 105 to 115 per cent. The danger signals which are represented by the double dots should at all times be visible. When they are no longer visible, then the dose has exceeded 135 per cent. of the standard skin dose, and represents an amount of radiation which will cause a burn."

When the application is to be made to a part where it is not possible to irradiate from different angles—as, for example, the breast—the proper distribution of the dose is obtained by increasing the "target skin distance," thus reducing to a minimum the difference in density between the rays falling on the skin and those reaching the farthest border of the disease.

The necessity of giving the full dose at one sitting is emphasized strongly by Scitz and Wintz. They say that a dose sufficient to kill a cell, if administered at one sitting, is insufficient if it be divided over a number of days, as in the intervals the cell has time partially to recover, and it may be, even to develop a certain amount of resistance or immunity. Considerable difficulty is sometimes experienced in getting the patient to lie quietly for the long time necessary, and no effort must be spared to have the patient thoroughly comfortable and resting in a relaxed position before beginning treatment. Sometimes vomiting sets in before the dose is completed and makes it impossible to give the full dose at one sitting. The question arises whether a narcotic should be used as a routine. It has not so far been my practice.

Of the patients treated for malignant disease between June, 1921, and May, 1922, 52 suffered from carcinoma and 8 from sarcoma. The parts affected were the breast, bladder, vulva, uterus, mouth, prostate, rectum, abdomen, larynx, neck, tonsil. It is unnecessary for me to say that the time is yet too short to speak of results except in the most tentative sense; but the immediate effects are very striking indeed, and I am of opinion that with greater experience even greater benefits will be obtained.

The results here reported are not so favourable as those reported from Germany. This is to be accounted for—at least in part—by the fact that in Germany patients are subjected to the treatment at a much earlier stage of the disease than in this country, and, owing to the longer time for which the method has been in use there, the operators are more experienced in the technique.

In the 16 cases of disease of the breast, whose histories I give below, the results are: In three the treatment failed entirely. In three there was great improvement (two have

since died). In nine the evidences of the disease have disappeared—that is, in 55 per cent. all sign of the disease is gone at present; these were all severe cases. In two only there had not been a previous operation; the rest were recurrences, and all were inoperable. Of the 16 three should perhaps not have been treated; they were apparently hopeless from the beginning. Excluding these, the evidences of disease disappeared in 69 per cent.

Of the three patients suffering from malignant disease of the bladder, one should perhaps not have been treated, as she was too ill. The other two have greatly improved but are not yet well, both having suffered from a hæmorrhage some months after the treatment was stopped. Both have had further treatment recently and appear to be well at present.

Of the five uterine cervix cases three should not have been undertaken on account of the extensiveness of the disease. (One of these was treated for the relief of pain only.) Of the two remaining one is apparently well, and the other very greatly improved. She is still under treatment.

Of the five rectal cases the disease was so extensive that complete recovery could not be expected, but three have very greatly improved.

Keeping in mind what I have already said regarding the shortness of the time covered by these notes, and the small numbers, and avoiding the use of the word "cured"—to use which under the circumstances would be unwise—I think a fair impression of the effects of the treatment in the cases reported may be got by tabulating them thus:

1. In 30 per cent. of all cases all evidences of the disease have disappeared.
2. If one excludes the cases that were apparently hopeless from the beginning the figure is raised to 41 per cent.
3. In 52 per cent. the benefits secured were very great in the way of relief from pain or discomfort, and of the patient being enabled to return to a more or less ordinary mode of life.
4. Excluding from the breast cases those that were hopelessly ill, 69 per cent. have shown complete disappearance of all evidences of the disease.

The author then gave detailed summaries of fifty cases, including breast tumours, malignant disease of the bladder, cervix, and rectum, and of the tonsils and larynx. He concluded as follows:

It will be seen that a number of cases were treated which appeared to be hopeless from the beginning, but these were undertaken, not with any hope of cure, but simply to relieve pain and the more distressing symptoms.

Finally, it cannot be too strongly insisted upon that it is impossible to attain any degree of success by this method unless one is prepared to spend much time and labour on details. The technique is difficult and requires constant attention. In the English translation of Voltz's valuable tables, edited by Dr. Reginald Morton, this point is emphasized, as the following extract shows:

"Probably the greatest danger to the future of the method lies in its being taken up by those who are unable or unwilling to give the time and skill necessary for its proper performance. The best results will be obtained only by those who devote themselves to this work to the exclusion of everything else."

II.—J. H. DOUGLAS WEBSTER, M.D., EDIN., CH.B.,

M.R.C.P. EDIN.,
Honorary Physician in Charge of the Department of Physical
Medicine, Middlesex Hospital.

As has been shown by x-ray spectrum analysis, from the physical point of view our discussion is concerned with the use of a radiation of a wave-length over ten thousand times shorter than violet light, violet light being four thousand of the Angström units of a ten-millionth of a millimetre (10^{-3} cm.). The waves we employ are 0.2 to 0.06 Å. U., so that one-half to one million of them could be contained in the diameter of a hair. Their half-value in water is 1.6 to 3 or more centimetres. They are obtained by different types and models of electrical plant, all capable of producing for hours on end voltages varying from 150,000 to 250,000 volts, and of x-ray tubes capable of a continuous output of from 1.8 to 5 milliamperes at this pressure, the skin erythema dose at about 9 inches distance being given in from 40 to 15 minutes. With these x-ray tubes and a filter of 0.5 mm. of zinc or copper or other equivalent an emergent beam results, which by passing through successive layers of body density is not further altered in quality—that is to say, it is a beam qualitatively homogeneous. By the prolonged labours of the physicists Dessauer, Voltz, and their co-workers, we

patients, as Krönig pointed out; and secondly, as Soitz and Wintz point out, those in whom the disease is too widespread—as, for example, when there are malignant ovarian growths with deposits in the pelvis and throughout the abdomen, and this especially if there is also ascites. In these cases to give a full carcinoma dose throughout both pelvis and abdomen would be impossible without causing severe general damage. Treatment of a part—for example, the pelvic deposits—may perhaps be undertaken in the hope of producing an immunity to the whole condition; but, so far, I have seen no case with ascites treated in this way in which any good resulted. As to cachexia, cachexia from the malignant condition should not be confused with the ill appearance which results from a septic mouth or other removable cause. A patient should have definite blood changes and a cachexia which does not respond to general measures before one refuses him the chance that radiation may do good, all other measures having failed. The clinical aspect is a wide one, including the question of radiation before or after operation (radiation before operation being largely done now in America), the general treatment advisable before and after the radiation, also the interrelations between us and most of the other branches of medicine and surgery. At present our position with regard to malignant disease is most sure when, remembering the immense variety of pathological growths, we endeavour to establish the use of radiotherapy as a valuable adjunct or alternative to surgery in various types and sites of growth; this, so far, has been done most successfully in the gynaecological sphere and in superficial malignancies, such as rodent ulcer. The future will show how far we can control leukaemias, mediastinal growths, and those in the gastrointestinal and other systems.

Next as to technique. As regards instrumental technique, the first essential is to know one's own apparatus and what it can do, and this with standard Coolidge, or long Coolidge, or gas tube, or Lilicufeld tube. The secondary voltage must be constant, and to ensure this either the town voltage should be measured to see if it varies or not, and be corrected if it is variable (some have done this by passing the main current through a large resistance so that it may be stabilized), or else the interruptor speed should be noted, for when the main voltage goes down the motor slows and the penetration rises as Schiempp has pointed out, and if this happens the scale on the switchboard showing the hardness is a much less reliable guide than the alternative spark-gap, as may easily be proved by anyone who experiments with these factors. As in some towns the primary voltage varies as much as fifty volts up or down, this is obviously a factor which requires attention. The newer Erlangen apparatus with a motor counter on the switch-table avoids this source of error.

As to clinical technique, first I should mention the preliminary iodoization with copper selenate, which at Erlangen has been so heartily recommended, especially in septic cases. I cannot dispute the clinical findings as to its benefit, but the theory on which it is based, that copper particles penetrate along with the positive current to a considerable depth (sometimes given as up to 12 cm.), I take leave very much to doubt. Dr. Turrell's experiments and reasoning appear to dispose of that claim, in my opinion; he has shown that the blood and tissue fluids rapidly disperse any inflowing ions. But that the galvanic current in itself may have a powerful effect in making the malignant tissue more radio-sensitive no one can deny, and Voltz recently has discussed this effect and shown marked cellular changes in the ovaries of animals resulting merely from the passage of a galvanic current. This question undoubtedly requires much further working out, as also the other aids or alternatives to radiation treatment, such as diathermy.

Next as to the use of radiation from a great distance—up to a metre. In my opinion this should be abandoned on the score of time and unnecessary expense in staff and apparatus; and another method of improving the depth dose be substituted—namely, giving the surface an artificial depth by interposing several centimetres of wax, paraffin, water, or the like. Dessauer in recent articles has referred to this method, which I started on my own account some months ago. He quotes Chaoul of Munich and von Viesner of Vienna as having started the method, but von Viesner's article I cannot trace, and all the literature I can find of Chaoul's on the subject refers to quite another method—namely, collecting the rays that would pass beyond the sides of the body, in laterally placed paraffin blocks, thus reflecting some of the more divergent rays back

on to the body, and increasing the intensity, especially at the sides of the area irradiated. This is quite a different method from the one I can recommend as the result of some months' experience, by means of which many of the distance doses recommended in the original Erlangen method can be reduced to half or less of the time necessary with the same results in the depth intensities. I was glad to hear from Dr. Casman of Antwerp, at the recent Radiological Congress, that he uses this method in breast and other cases, and is very well satisfied with the result.

As to the use of small fields, it is very difficult to orient them so as neither to have too much overlapping nor to miss out areas altogether. To avoid these technical errors, and to calculate the depth dosage as accurately as possible, I suggest that every case treated should have sectional drawings made to scale, with the ports of entry mapped in, and doses at each successive centimetre written in, and this in at least two diameters of the body or area irradiated. Holfelder has devised little gelatine shapes giving the depth doses for different fields and percentage depth doses, and these should be useful for quick calculation, as overlapping they obliterate marks on the paper below corresponding to different intensities.

The method of scaled sectional drawings in some form or other must be recommended as the only accurate one; also in radium work this should apply. Professor Lazarus-Barlow has told me that in his recent visit to America he found that this is the method adopted in each case in the radium work at most important clinical centres. Perfect accuracy is of course unobtainable; the tissues, from their varying blood and mineral content, cannot have a scattered radiation, or absorption with secondary characteristic and beta radiation, exactly as that in water. Nor can one easily calculate the depth doses when air-containing organs, like the lungs, bowels, larynx, etc., are concerned; also bones, having an absorption like aluminium, complicate the calculations of pelvic doses and those in the lungs, spine, or head. The biological factors in this way alone elude physical powers of measurement, apart from other limitations of the physical point of view. In the measurement of depth intensities, working on Voltz's or Dessauer's tables, and using a superficial layer of wax, a slide rule will be found most convenient in calculating the proportional doses to those in the tables, and in many cases to give several full skin doses converging will be found to give too much of a deep dose, and this is especially the case where thin patients are being treated. It has been indeed usually in very thin patients that bowel and other damage has been observed, and this may have been a result of a wrong routine use of the typical Erlangen technique, which applies only to stout Bavarian patients! The only way to avoid overdoses is by careful measurement in each case.

Professor Wintz and Dr. Langer have a wonderful system of radiological technique which they have evolved practically for all parts and suitable conditions of the body, and incidentally this technique (until Dr. Langer publishes his long-expected book) can only be learnt by a visit to Erlangen or by instruction from someone who has been there. I am, however, strongly against Langer's ingenious method of localizing fields—the small fields, for example, on the cervix or pylorus, or the large fields as on the chest—by screening to centre or delimit the area irradiated. When this is done with the tube running at high voltage the observer is exposed to the great amount of scattered radiation in the close proximity of the tube. Professor Russ has very kindly examined this electroscopically, and in his opinion he considers it a very dangerous method for radiologists to use. Personally I have never done it without substituting a soft tube placed with its focus at the same position in the tube box as the high-voltage tube's focal point. This exchange only occupies a few minutes, and can be recommended to all who employ the original Erlangen methods, otherwise a localizer, like Campion's localizer, can easily be constructed where accurate centring has to be carried out. With the large fields in the Warnekros-Dessauer methods, their plan of substituting for the tube a pointer which gives the area irradiated is a most valuable assistance to accurate technique without running the risk of exposure to radiation. The exposure to radiation in tube-testing or reading the small ionization-quantimeter can also be lessened in various ways—for example, by moving the Kienböck strips on to the surface of the wax while fixed in the end of a long rod, or reading the electroscopa scale from a distance by mirror reflection. A small point in technique is to cover the metal filter above and

below with colluloid, as Warnokros does; this can be heartily recommended: above it prevents the tube sparking to the metal, and below it acts as a filter for the soft rays from the copper or zinc.

I see no reason why the Erlangen wave-length should be used in all cases; in particular I am doubtful of its value in breast prophylactic work, as the damage to the blood in the lungs and heart may counterbalance the likelihood of good resulting to a possible pleural invasion. Personally at present I use a standard Coolidge run at 11½ to 12 inches spark-gap, giving a depth dose of about 12 per cent. at 10 cm. deep (5 mm. filter) for prophylactic breast cases; or use the Erlangen wave-length on to a large primary growth, and the Coolidge on to the outlying areas.

The Erlangen scheme of a six or eight weeks' interval between doses should not be taken too literally. Surely much must depend on the type and speed of development of the growth as well as on the general condition of the patient. Between the one absolutely maximum cancer dose ideal of Krönig and Warnokros, and the old method of multiple smaller doses, repeated at short intervals, which Kugery in a recent note says he has been trying to establish experimentally, as the best method, those of the Erlangen school occupy a middle position: they give submaximal doses and repeat them (it must be remembered that the Erlangen "skin mit dose" is smaller than the maximal skin dose of Warnokros); it is certain that much work yet remains to be done before we can decide which method is the best, or in which cases which should be preferred. Experiments like those of Lazarus-Barlow on the rat, on columnar and squamous cells, suggest that squamous-celled types of growth would respond better to small doses frequently repeated, and columnar to maximum doses. The subject is being experimented with; radium emanation "seeds," for example, provide a ready means of trying long-continued chiefly beta radiation of small intensity, the results of which must have a bearing on x-ray work, and may show that the method Löwenthal and others have employed of giving x radiation an hour or so daily for eight or more days through a filter of a quarter of a millimetre of lead may in certain cases be the best method of x-ray treatment. (Christen has estimated the half value for radiation after 0.25 mm. Pb as 10 cm. in water.)

The whole subject is thus seen to be one in which as yet sure conclusions are hard to find. Certain is it that the application of deep radiation treatment is not one which can be undertaken by untrained medical men, or by nurses or laymen without the probability of grave damage being done to patients. A communication I had a few days ago from a no doubt very well-informed one of the colonies who styles himself "a patient" to a hospital, though he is an electrical engineer, asking for the fullest details of the instruments and technique necessary for deep therapy, and for the results which are being attained, seems to me rather ominous. Before a German medico-legal congress last year I heard Professor Wintz in an address very strongly emphasize this danger, that the apparatus may come into the hands of those who are not properly qualified to use it. However, there are dangers in the use of every potent remedy as in the use of most modern inventions, and it is easier to point to possible abuses than to suggest a remedy.

The main fact is that we are now witnessing a series of notable advances in x-ray instrumentation, and in methods of quantitative measurement of depth radiation, and these must in a short time result in a greatly increased knowledge of the subject. As to results, I am quite satisfied that some of the beneficial effects I have already seen could not have been obtained with any other method of treatment, and if the already published results receive confirmation as time goes on we shall undoubtedly have achieved a very important stage forward in the conquest of malignant disease.

III.—F. HERNAMAN-JOHNSON, M.D. ABERN.,

Director, X-ray and Electrical Service, French Hospital, London.

I propose to confine my remarks to the statement of certain fundamental principles—or, at least, what I believe to be such. Some of these, while they were more or less accepted a few years ago, appear to be in need of reassertion.

A cancer cannot be clinically considered apart from the tissues amongst which it grows, or from the patient as a whole. This means that the effect of any given dose of x-rays upon a cancerous tumour is composed of (1) the direct effect upon the malignant cells; (2) the reaction of the

normal surrounding tissues; (3) the general constitutional response.

Now, the effect upon the tumour varies not only with its histological structure and with its position in the body, but also with the particular moment at which it is attacked. In thinking of tumours we should try to substitute in our minds a dynamic for a static conception. You have all seen by the aid of the cinematograph a plant growing from seed to flower in a few moments. Imagine this process applied to histologically similar tumours, and suppose it to display differences in mitotic activity, as well as in general growth. We should then see that no two were alike—and even then this unlikeness would not be fully made manifest, for those subtle divergences covered by the word "metabolic" cannot be made visible, even with the microscope.

I come next to the surroundings of a cancerous growth. That they play an important part in its disappearance under radiation cannot be doubted. A rodent ulcer—which is really an ulcerated tumour—is a truly malignant condition although it does not tend to form metastasis. So long as it invades only the soft parts, it may usually be made to disappear by almost any method which stimulates the tissues round about it. Some years ago I tried to see how minute doses of x-rays would affect rodent ulcers, and found that, as long as any action at all could be observed, it was a favourable one. But once let the rodent invade cartilage or bone and nothing save excision or diathermy is of avail. Yet the tumour has not changed, but only its habitat.

Finally, there is the patient to consider. It has long been observed that an anæmic patient will not respond well to x-rays; and the rapid spread of metastatic growths after a serious attack of influenza is a well-known phenomenon. The slowness of most forms of cancer in old age has long been remarked on. On the other hand, the part played by worry in lowering resistance to malignant disease cannot be disputed.

If it be granted that the effect of an x-ray exposure is indeed determined by factors so numerous and so variable, it becomes difficult—for some of us, impossible—to accept the doctrine of the single lethal dose. I question it, in point of fact, this doctrine is still held by those who only a year ago advocated it so strenuously in the medical press, and not in that press alone. One hears of precautionary doses after six weeks, and of yet further "precautions" at later dates. But if repetitions every six weeks, why not every six days? One give up the idea of the "knock-out blow," and the precise size and spacing of divided doses offers wide and legitimate scope for individual preferences.

It used to be accepted as axiomatic that cancer cells—apart from certain very resistant types—were depressed by x-rays more than their surrounding healthy neighbours, and that in some cases a dosage detrimental to malignant cells might actually stimulate normal ones. If this is true—and for my own part I do not doubt it—it follows that a cumulative effect may be obtained by repeated dosage.

The doctrine of the "small stimulating doses"—that is stimulating to cancer cells—has, in my opinion, done at immensity of harm. It has frightened men in small hospitals possessing only 12-inch coil outfits from treating breast cases, in the belief that they would do harm. Now, there is no radiologist of experience who does not know that we were often able to keep breast cases in comfort for years, long before the high-voltage outfits, or even Coolidge tubes, were ever heard of. Most of us have seen pain disappear and palpable growths melt away under what would now be called primitive methods. On the other hand, I cannot recall any instance in which such treatment appeared to make patients worse, even when it did no apparent good.

For the past year I have had in my private practice apparatus for the excitation of a new model Coolidge tube in oil at a potential of 230,000 volts; and I have applied it to many cases of inoperable or recurrent breast cancer. During the same period I have treated an approximately equal number of similar cases at the French Hospital—in the latter case being limited to a voltage of about 160,000.

I cannot honestly say that the extra seventy kilovolts appears to improve results. The twenty cases of breast carcinoma which I have had under observation for purposes of this test are all still alive and doing well after periods varying from a year's to two months' treatment; and I have patients treated under the old methods still going about their affairs five years after the original recurrence.

I hasten to say that I have not tried my high-voltage apparatus on any carcinoma mammae case by the method of

the single massive dose. It is generally agreed that the procedure seriously affects the blood of the patient and lowers the resistance for some weeks to metastatic invasion. On the other hand the graded dosage system causes the patient to improve in every respect almost from the start, and without any intermediate period of depression.

The recurrent or inoperable breast case properly treated by graded dosage does not ultimately die from visible or palpable local tumour, but from metastatic invasion of lungs, liver, spine, or ovaries. Can massive doses applied to the original growth prevent this termination? I do not think it will be claimed that they can. On the other hand they may hasten it. But the graded dosage actually raises general body resistance to cancer, and therefore, for a time at least, prevents its generalization.

The last thing I want to suggest is that the x-ray treatment of breast cases should be undertaken by amateurs, or that research should not be vigorously prosecuted by the newer methods. But when a man has been getting good results for years with an ordinary outfit in a hospital which is unable to afford a high-voltage apparatus, he should not be frightened into giving up because of the doctrine of the stimulating dose. There never was a more unsubstantial bogey raised in medicine, yet it has in all probability deprived many unfortunate people of the mitigation of their sufferings offered by x-ray treatment as it has been carried out in this country for the past dozen years.

When I come to speak of uterine cancer I am on ground less firm. In my hands the older methods have often given considerable relief, but I have generally regarded such patients—always, of course, either inoperable or recurrent—as having not more than a few months of active life before them. There would appear to be hope that by the newer methods this expectation of life will be increased.

The early, still operable, case of carcinoma of the cervix is the one most suited for Erlangen methods, and is the type on which their reputation is really based. That this form of cancer may be made to disappear by massive doses, and that the patient may be given a further lease of life, is beyond question. This may also be accomplished by surgery—whose record is not, however, at all brilliant in this respect. The ultimate results of intensive x-ray therapy may be far from good and yet be superior to those of surgery. It is a matter of statistics. If a man has an operable carcinoma of the bowel my advice to him would be, "Have it cut out." If he has a sarcoma almost anywhere I should say, "Do not let the surgeon near it, unless, perhaps, to put in a radium tube." But if a woman came to me with early carcinoma of the cervix and asked my advice as to whether she should have an operation or treatment on the lines recommended by Professor Wintz I could not, at the present moment, give any decided opinion.

Finally, I wish to say that if I am not as impressed as some are with the results of Erlangen treatment it is not because I doubt that many of these results are excellent, and, in some cases unique, but because I am familiar with the extraordinary benefits, amounting not seldom to clinical cures, which methods long in use in this country have to their credit. I welcome the high-voltage outfit as a great advance in instrumentation, and the work now being done at Erlangen in the way of preparing the patient and sensitizing the tumour by electrical methods previous to its exposure to x rays seems to me to promise much. It proceeds along the threefold line of attack which was referred to at the beginning of my remarks. In the case of a protean malady like cancer combined treatment in the widest sense can alone hope to succeed.

DISCUSSION.

Dr. W. MITCHELL (Bradford) said that he shared to a large extent Dr. Hernaman-Johnson's scepticism with regard to the stimulating dose. He had administered about 9,000 treatments a year with the older type of apparatus, and had not seen any stimulation produced, but rather the reverse. Sometimes he had observed a rapid metastasis follow surgical treatment. He had known cancers of the breast to lie quiescent for many years, and then, a very few weeks after operation, rapid metastasis occurred—whether due to mechanical injury or to a depressing effect on the body tissues he could not say. If radiologists were accused of stimulating cancer by their methods, then surely surgeons might be accused of doing the same kind of thing. As for Erlangen methods, an apparatus for deep treatment had been

installed at his institution, and he had treated about one hundred cases, post-operative, recurrent, and non-operative. In passing he would recommend that before a case was undertaken a skiagraphic examination of the lungs should be made, and if the lungs were affected the case should be left alone. The speaker then gave particulars of some of his cases. Those which were handed to him were mostly surgical derelicts—cases which were absolutely hopeless from the beginning; it was clearly impossible properly to estimate the success of Erlangen methods until surgeons handed over their cases much sooner. It was useless to try to treat cases in which the pelvic viscera were largely involved or the vagina stopped up with a large tumour. He had had recurrent cases in the early stages when there had been nodules of the size of walnuts in the vagina, and in which good results had been obtained. He had also had four or five cases of carcinoma of the vaginal walls, one patient being a woman of 60, who was now quite well. In one case of carcinoma of the stomach, where the patient had died, the *post-mortem* examination had revealed extensive disease, not alone of the stomach, but of the duodenum, the liver, and the pancreas, with carcinomatous invasion of the peritoneum, so that there was not much chance in that case. He was satisfied that the method had a useful future, but it required a very large amount of time if the work was to be done thoroughly.

Dr. WOODBURN MORISON (Manchester) agreed with Dr. Hernaman-Johnson in his remarks about stimulating doses. He had never seen any cancer stimulated by the ordinary dosage such as the radiologist had been using for years past—a full pastille dose through a filter. He had been interested in the treatment of rodent ulcer by radium; at the present time, in Manchester, the tendency was to use unscreened radium in these cases. He believed that the direction of development for radiation treatment in the future would be in the selection of the wave-length for different tumours and for different parts of the body.

Dr. GIBSON GRAHAM (Glasgow) said that his experience was that x rays in too small doses would stimulate growth on the extending part of an ulcer.

Dr. A. R. HALLAM (Sheffield) confirmed Dr. Graham's view, as the result of many years' experience of rodent ulcers. He had seen people who had had a rodent ulcer for years, which made practically no progress, and then, after one or two small x ray exposures, it disappeared for a short time, only to show later a rapid increase of growth.

Dr. HERNAMAN-JOHNSON said that although it might be argued theoretically that radiological treatment could stimulate cancer growth, yet in clinical practice the treatment was not found to have that effect.

DISCUSSION ON THE VALUE OF GAS INFLATION IN X-RAY DIAGNOSIS.

OPENING PAPER.

BY

F. HERNAMAN-JOHNSON, M.D. ABERD.,
Director, X-Ray and Electrical Service, the French Hospital, London.

[WITH SPECIAL PLATE.]

Historical.

THE idea of obtaining contrast by the injection of air is, of course, as old as radiography itself. The first man who looked at a normal chest and saw the heart standing out clearly against the almost transparent lungs must surely have been struck by the beauty and clearness of the picture; and when he proceeded to screen the abdomen could scarcely fail to wish that nature had there provided equal facilities for the elucidation of disease.

No very long time elapsed before, as a matter of chance, radiographs were obtained in which either the lower border of the liver, or the spleen, or both, were outlined with considerable clearness by collections of gas in suitable parts of the alimentary tract. This observation was followed by deliberate attempts to throw light upon abdominal problems by the artificial inflation of the stomach, colon, and bladder. In a work entitled *The Röntgen Rays in Medicine and Surgery*,

written by Williams of Boston, and published no less than twenty-two years ago, are to be found descriptions of such procedures, and also of the bismuth meal and the bismuth enema. The "normal stomach" as described in x-ray textbooks of the present day was figured by Williams in 1899, and to him rather than to later German workers should go the credit of originating the opaque-meal idea. In fact, there are very few modern developments, whether of instrumentation or of diagnostic technique, that are not foreshadowed in this book; but I regret to say that I have been unable to find in it the germ of the idea of the deliberate inflation of cavities other than those of the hollow viscera.

The injection of gas into the pleural cavity for therapeutic purposes and the control of the procedure by fluoroscopy were well established early in the first decade of this century; but the idea of inflating the peritoneum for diagnostic purposes would really appear to have originated in Germany within the past ten years. Weber, in 1913, appears to have been the first to do so with the deliberate intention of improving radiographic contrast; and Goetze published the first extensive report on the subject, together with some plates and diagrams. From Germany the method spread to America, and so far as I am aware the first published cases in England were done at St. Bartholomew's Hospital less than two years ago.

In addition to the distension of the hollow viscera, gas inflation for diagnostic purposes is now employed in the peritoneum, in the perirenal space, in the joints, and occasionally in the ventricles of the brain. All of these procedures are germane to the present discussion, but I have not personally sufficient experience of the method as applied to the joints or to the brain to say anything useful; and upon the inflation of hollow viscera I intend to touch only briefly.

Inflation of Hollow Viscera combined with Pneumo-peritoneum.

Inflation of the stomach with some effervescent powder is a well-known proceeding, to which the objection is often raised that, the amount of distension not being under control, there may be some risk of rupturing an ulcer, should such be present. Recently, in conjunction with Dr. Ernest Young, I have made some experiments upon inflating the stomach and duodenum through a fine duodenal tube, which Dr. Young has kindly passed for me. So far as the duodenum is concerned, the gas appears to distribute itself too quickly into the small intestine to permit of useful outlining. It may be possible to devise some pneumatic form of blockage; but, meanwhile, the method furnishes a safe way of inflating the stomach under direct fluoroscopic control. Incidentally, it has been shown that the metallic head of the tube may be in the duodenum a very considerable time before an alkaline reaction is obtained from the fluid syphoned up.

The value of stomach inflation would appear to me to lie in this: that, when combined with peritoneal inflation, it may enable us to recognize comparatively small changes in thickness in the anterior wall of the stomach. Those who have studied lateral radiographs taken after peritoneal inflation will realize that extremely small differences in density can thus be demonstrated.

Uses of Peritoneal Inflation.

Coming now to the uses of peritoneal inflation, one has to ask oneself, What lesions can be demonstrated by this procedure which cannot be diagnosed by other means? A study of Fig. 1 (see Special Plate), which is a composite radiograph of the whole peritoneal cavity in profile, will help us to answer this question in part. Starting from the diaphragm, you see the liver clearly in profile; and irregularity of size or shape would be at once apparent. It is true that we see the viscera on one plane only, but we may, if we wish, take other plates with the patient rotated through various angles, and we can also get the lower border of the organ outlined in the posterior view. A liver which will pass these tests is presumably free from deforming lesions, though we cannot say absolutely that it is in no way diseased. The air space between the intestine and the abdominal wall is here free from abnormalities with one exception. That is a thin shadow band which crosses the space some two inches below the umbilicus. This was diagnosed as an adhesion between the intestines and the abdominal wall.

The patient had had a pan-hysterectomy done ten years previously, and since then had suffered a great deal from abdominal pain. Below and to the left of the umbilicus was felt a "lump," which was tender to touch, and which the patient said was growing larger. The "lump" was

examined clinically by a well-known surgeon, who confessed himself unable to give a definite opinion as to its nature. With his approval, a peritoneal inflation was carried out, with the result I show you. This enabled me to say that the swelling in the left abdomen was not caused by the presence of a tumour. An operation was performed at which I attended. Adhesions were present to an unusual extent, so much so that the surgeon occupied nearly two hours in dissection. The patient made an uninterrupted recovery, and it may interest the Section to know that application of hard rays to the abdomen were given during convalescence with a view to preventing the re-formation of adhesions. Up to date (four months) the patient remains free from pain; and her "lump" has not returned. No doubt it was caused by a more or less permanent collection of gas, the result of adhesions.

By way of comparison, I show you a slide (Fig. 2) which represents a perfectly normal lower abdomen seen in profile. You will note the entire absence of any shadows across the air space.

The next slide (Fig. 3) I am able to show you through the courtesy of Dr. Finzi. It represents an abdominal tumour seen in profile. An obvious criticism is that in all probability the diagnosis could in this case have been made by other means. Perhaps this is so, but the size and relationships of the tumour as shown in this and other views could not in any other way have been ascertained with the same exactitude. Also, it is necessary to learn the alphabet of a new subject, and a radiograph such as this, in which the appearances are perfectly definite, is of great value to the student. For it must be obvious to anyone who considers the matter that a tumour of the same nature, but only a quarter or even one-eighth as large, would have been just as easily demonstrated. Or, to put it another way, if this patient had been examined by pneumoperitoneum when a tumour was only suspected clinically, proof of its existence would have been furnished.

Another field of usefulness for peritoneal inflation is in the diagnosis of gynaecological conditions. The method will enable a diagnosis to be made while the case is still clinically doubtful. In this country we are as yet only feeling our way as regards these inflation methods, but Dr. Carolli, at his demonstration before the Royal Society of Medicine last autumn, showed us several plates in which the diagnosis of lesions in the ovaries, Fallopian tubes, or uterus was actually made by him at a time when it was impossible to arrive at any certainty by other methods. In one particular case a two months' pregnancy was demonstrated by reason of the characteristic type of enlargement of the uterus; this is surely a great triumph of radiological technique.

To sum up, comparatively small deviations from the normal in the size, shape, or relations of the viscera within the peritoneal cavity can be demonstrated by the inflation method. Adhesions are made visible, and solid tumours at an early stage of their growth can be clearly seen. There is also some hope that improved technique may enable one to detect cancerous infiltrations of the walls of the alimentary tract.

Risks.

It can scarcely be denied that the procedure of peritoneal inflation represents a startling advance in diagnostic technique, with which the introduction of the opaque-meal method is alone comparable in individual importance. Yet there is, unfortunately, a pronounced difference in the two cases. The opaque meal and enema are free from risk, or nearly so. Peritoneal inflation is not free from risk. Dr. Carolli informed us that he had done over 700 cases, with only one (non-fatal) mishap. But others have not been so fortunate. James T. Case, in a recent review of the subject, has collected records of four deaths. Of these, one was due to the introduction of oxygen into the spleen; one to peritonitis; and in the other two the patients became cyanotic, and collapsed a few seconds after the introduction of the needle, and before any appreciable amount of gas had entered the peritoneum. In neither instance was necropsy permitted.

Case offers no definite opinion as to the cause of death in these patients. Choyce² states that in a certain small percentage of people the diaphragm is perforate in places, so that there is communication between the abdominal and thoracic cavities. Under such circumstances, pneumothorax would result with possible embarrassment of the heart. If such a condition could be demonstrated fluoroscopically one might be called upon to introduce a trocar into the pleural cavity and aspirate the gas. But while this is a possible

¹ BRITISH MEDICAL JOURNAL, December 17th, 1921, p. 1037.
² Private communication to author.

explanation of the fatalities which Case records, it does not seem to me probable, as the cyanosis occurred almost immediately. Personally I should be inclined to class these with the recorded instances of death following simple paracentesis of the pleural cavity. The nearest we can get to an explanation is to say that the slight trauma to the sensitive pleura or peritoneum is sufficient to produce reflexly cardiac disturbances, which may be so severe as to prove fatal.

The important point to bear in mind is that there is no known way of avoiding such accidents.* They are fortunately extremely rare, but must nevertheless be reckoned with.

Importance of Careful Technique.

Apart from the above, safety may be secured by careful technique. The use of a fine needle is most desirable. I prefer to make my puncture through the belly of one of the recti muscles, about two inches below the level of the umbilicus. One can soon learn to feel when the needle passes through the posterior sheath. The open end of the needle should then be watched to see if any blood comes out. If so the needle should be reinserted, otherwise one may inject gas into a vein. Gas should then be introduced slowly from a suitable apparatus (Fig. A). If the needle is still in the muscle, pain will be produced at once.

FIG. A.—Diagram of inflation apparatus.

If, however, the point has pierced the abdominal wall it must be in either (1) the peritoneal cavity, (2) some solid organ which is enlarged or mal-placed, (3) the substance of an abnormal growth, or (4) the lumen of the bowel. Of these the last-mentioned contingency can happen—apart from gross carelessness—only if the intestinal wall is glued to the abdominal parietes by adhesions at the site of the puncture. In one of my early cases, as I did not recognize by the screen what was happening, I interpreted the folds of the bowel as adhesion shadows. The patient passed most of the gas per rectum within a few moments, and was none the worse. Subsequent operation showed the intestine to be, as it were, plastered on to the anterior wall of the abdomen, and it would probably have been impossible to obtain a proper pneumoperitoneum. Puncture of the bowel wall under such circumstances is harmless as regards risk of infection of the peritoneum, as the puncture, even if it remained patent, which it does not, is innocent of any communication with the body cavity.

Puncture of an hypertrophied spleen, or of a large tumour, is not likely to happen if the inflation has been preceded, as it always should be, by careful clinical investigation and radiographic examination along ordinary lines.

Having made sure that the gas is really passing into the peritoneal space, one may proceed to inject slowly and continuously, checking the process from time to time by screening. The amount to be introduced varies according to several factors, but, generally speaking, about three litres is sufficient in an adult of average size. When there has been previous ascites as much as ten litres has been tolerated without discomfort. On the other hand, if there is pain or

distress, no attempt should be made to reach any special academic limit. If pain is complained of between the shoulders, Carelli's recommendation to tilt the patient upwards from the feet will be found useful.

There are many other details of technique which should be mentioned, but time does not permit of their consideration.

Two further dangers other than those previously mentioned must be briefly touched upon. The first is the risk of causing peritonitis. This can be minimized only by the most careful attention to asepsis. The second is the possibility of causing damage by the mechanical effects of intraperitoneal distension. It is quite obvious that protective adhesions may be broken down, and that in some instances virulent septic organisms, previously walled in, might be let loose to play havoc in the peritoneum at large.

The immediate after-care of the patient is of great importance. If CO₂ be used there is no need to deflate, as all feelings of distension will have passed off in from one to two hours. It is, however, in my opinion, essential that the patient should remain in the horizontal position for several hours, preferably for a complete day. This means that the examination should be carried out upon a wooden stretcher which fits the x-ray couch top, and which enables the patient to be carried back to bed without disturbance. If such cases are examined in private consulting rooms they should be sent at once to a nursing home in an ambulance. They are, in a sense, surgical risks, and must be treated with due respect.

I have no sympathy with the cry that only a professional surgeon should do the inflation. If the radiologist cannot do it, he has no business to have a medical qualification. But I do not think that the radiologist alone should ever decide that the procedure is necessary. Another medical man should always be associated with him, and they should make quite sure (1) that a satisfactory diagnosis cannot be made without pneumoperitoneum, and (2), in cases where an operation would appear to be a necessity in any event, that the inflation is likely to furnish the surgeon with advance information of sufficient value to justify the slight but undoubted risk involved in the procedure.

If the radiologist honestly fulfils these conditions precedent and keeps his patient under observation for at least forty-eight hours in such surroundings that a laparotomy can, if necessary, be performed at short notice, he can face risks with as clear a conscience as that of the renologist or pathologist who carries out spinal puncture after being duly convinced of its necessity.

Perirenal Inflation.

I propose to devote the remaining few minutes to some remarks on the method of perirenal inflation introduced by Dr. Carelli of Buenos Aires. You will perhaps remember that Dr. Carelli gave the first demonstration in this country in my department at the French Hospital in London in November of last year. A detailed account of his procedure, as it appeared to me, was published, together with reproductions of some of the radiographs obtained, in the BRITISH MEDICAL JOURNAL for January 21st, 1922. I cannot here repeat the substance of this paper, but will confine myself to summarizing the results of my personal experience with perirenal inflation since that time.

To begin with, it should be clearly understood that the technique is not easy. I have myself gone into the colon by mischance, and on the Continent I understand that the pleural cavity has been entered on more than one occasion. Such accidents are the results of inexperience. Dr. Carelli recommends that the needle should be directed vertically downwards so as to touch the tip of the second lumbar transverse process, then turned somewhat upwards and outwards so as to slide past the end of the bone. It is difficult to gauge the correct angle, and I now prefer to start half a centimetre beyond the tip of the process, and to direct the needle point slightly inwards so as to touch it. The object of this is to secure a landmark, especially as to depth. Having obtained my bearings, I then cause the needle to resume the vertical position and push it in another centimetre. A very usual mistake is to insert the needle too deeply before making test injections. (For rough sketch of relations see Fig. B.)

One should now watch to see that no blood wells out of the socket of the needle. An ordinary record serum syringe previously filled with gas is then fitted into the needle socket. The joint must be airtight. Quick pressure is made on the piston, and one of three things happens:—(1) An elastic resistance may be developed. This means blockage of the

* Since the above address was delivered I have been concerned very much with this question of possible peritoneal shock, and have adopted

SS of
36 of
date 1

gas in a rubber bag before connecting it to the apparatus. I have used a coil of metal tubing which is heated by boiling water. The gas real there are no complications in this twofold precaution—anaesthetization before puncture and the introduction of gas at approximately blood heat—one hopes to reduce the risk of peritoneal shock to a point when it need not be seriously considered.

needle, and a fine obturator, definitely longer than the needle, must be passed down it. This generally suffices, but sometimes it is necessary to inject a few drops of sterile saline gas goes in easily, but produces a sharp muscular distension, and is an indication for pushing the needle in a little more deeply. (3) The gas goes in easily, and no pain is produced. This is as near an indication as we can get that the perirenal space is reached.

FIG. 11.—Transverse section of body through kidney region, showing needle in position for perirenal inflation (modified from Gray).

We now connect to the main apparatus, and introduce about 50 c.cm. of gas. Then, using the two-way stopcock, test the manometer readings. The column should show increased pressure at inspiration; if by any chance one is in the pleural cavity pressure is diminished when the patient draws in his breath. In my experience manometer readings are not obtained until a certain amount of gas has been injected, although I understood Carelli to say that often the fluid column moved as soon as the needle entered the perirenal space.

It is necessary to inject at least 500 c.cm. of gas—a little more will enhance the contrast obtained. There should be practically no sensation at first, but subsequently a feeling described variously as "pressure," "distension," or "dull aching" is complained of. This is not of sufficient intensity seriously to inconvenience the patient. After about half the proposed quantity has been injected, the process should be checked by screening. It must be remembered that a considerable length of needle is sticking out, which must not be knocked in the dark.

A simple device like a miniature table, which straddles the patient, its legs resting on the couch on either side, is used to avoid accidents (Fig. C). This is put in place before the lights are turned off and the screen is rested on it. One can then examine freely, and it is generally possible to decide whether the gas is correctly outlining the kidney. If so, the remaining amount is injected, the needle is removed, and plates are made in the ordinary way. These should be taken both from below upwards and from above downwards, the reason being that the views are by no means identical, and that points missed in the one position may show in the

FIG. C.—End-on view of couch with screen on supporting table.

other. I show you now (Fig. 4) a case which Mr. Mortimer Woolf kindly asked me to examine for him. Here, besides the large obvious calculus, a cluster of small stones is visible. In this plate only three separate small shadows are seen; but in the next (Fig. 5) four small shadows are seen. Obviously there are cases in which exact knowledge as to the number of small stones present in clusters may be of great surgical importance.

There is just one other point of technique which I have found useful, and which I will briefly describe. In fat people, and in cases with lateral curvature, it is necessary to know in advance the exact position of the second lumbar. This is best ascertained by fixing on to the patient's back a half-plate-sized film in a tight-fitting black envelope. It can be stuck on by pieces of strapping, and its outline marked in ink on the skin. An exposure is then made, the film is developed, fixed, and dried in spirit. A needle is stuck through the image of the transverse process, so that the point just protrudes, and the film is replaced on the patient so as to coincide with the original marks. The skin is then pricked slightly with the needle and the film removed. If now iodine is rubbed on the skin over the needle prick, the latter shows as a permanent dark speck, which forms a valuable landmark. Apart from this special technique, no case should be examined by perirenal inflation which has not previously been radiographically examined in the ordinary way.

The advantage of being able to show the complete kidney outline, together with that of the suprarenal capsule, need not be laboured (Fig. 6). It will often in itself clear up a doubtful diagnosis; and when combined, as Carelli suggests, with gas inflation of the ureters and pelvis, must leave little to be desired in the way of x-ray demonstration. The after-effects of perirenal inflation, provided CO₂ be used, are, in my experience, slight, and no harm appears to result from letting patients walk about soon afterwards, although one does not permit this if one can help it.

DISCUSSION.

Mr. J. MAGNUS REDDING (Guy's Hospital) said that several factors had to be taken into account in assessing the value of any method of diagnosis: (1) the safety and ease of the procedure; (2) the scope of usefulness of the method; (3) the degree of accuracy in diagnosis; and (4) the value of the method compared with other methods of investigation. It was established beyond doubt that the presence of oxygen in the peritoneal cavity in large quantities was unaccompanied by any grave ill effects. The apparatus used in his own procedure of inflation consisted of two parts which, with the object of maintaining a strictly aseptic technique, were kept quite separate until the time for inflation had arrived: (1) A cylinder of oxygen with a long rubber tube, a considerable length of which was coiled into a large glass jar filled with very hot water. (2) A filter—a glass tube with a bottle neck at each end, tightly packed with cotton-wool; a short length of rubber tubing, one end of which was subsequently fitted on to the filter, the other end being provided with a hollow metal spigot; and a spinal anaesthesia needle, into the base of which the spigot fitted: these three pieces of apparatus were sterilized by dry heat. The skin of the abdomen was painted with iodine over a fairly wide area around the umbilicus, and sterilized towels were arranged around the site selected for puncture. Unless there were contraindications, puncture was made through the rectus, about one inch below the umbilicus and one inch to one or other side of the midline. The track proposed for the puncture was infiltrated with a local anaesthetic, and after a short period had been allowed for this to become effective the spinal needle was thrust slowly straight downwards. It was important to feel the very considerable resistance which was imposed by the sheaths of the rectus. The sheaths of the rectus were pierced by slow, steady pressure, and immediately after the posterior sheath had been punctured a very slight resistance was felt, accompanied possibly by a transient sensation of pain. Oxygen was then slowly turned on. He made no attempt whatever to measure the quantity of gas introduced, but he continued inflation until the patient complained of slight discomfort, upon which he withdrew the needle. He adopted this procedure because he thought the more gas the better; and the quantity was necessarily limited by the patient's tolerance. After the needle was withdrawn the puncture was sealed with gauze and collodion, and the patient turned

on to the abdomen. He had not found it necessary to wait before proceeding with radioscopic examination. Preliminary radioscopy was employed to make sure that the structures which it was desired to investigate were well enveloped in gas. The prone position was advisable as a preliminary, and this was afterwards modified to allow the best possible envelope of gas to surround the different structures. Radiograms were always taken, and ultimate diagnosis rested chiefly on these. The positions generally used were:—Liver and spleen: shoulder somewhat raised; prone. Kidneys: lateral. Antero-posterior views. Pelvic organs: prone; pelvis raised; also lateral antero-posterior views with pelvis raised. Double-screen films with short exposures were advisable, and the breath should be held during exposure. He attempted the withdrawal of gas only when the patient was complaining of some discomfort, for in his experience it was impossible to withdraw anything like all the gas through the needle within a reasonable space of time. The patient was invariably sent back to bed, with instructions that he might sit up when he felt inclined. The gas was usually absorbed within forty-eight hours or rather more, and appeared to be absorbed more quickly by children. He was convinced that when oxygen was used for injection patients should not be dealt with as out-patients. The effect on the patient was often painful and sometimes distressing. Pain was very much greater on movement, and especially on elevation of the shoulder, owing to traction on hepatic and other ligaments. Movements should therefore be restricted to the minimum. The pain and discomfort only lasted an hour or so if the patient remained recumbent, and there were as a rule no other ill effects. Unavoidable mishaps included puncture of structures adherent to parietal peritoneum where needle was inserted. No modification of apparatus could possibly eliminate the risk of entering the gut in these cases of adhesion. The actual danger appeared to be slight, but the results were exceedingly uncomfortable for the patient, and might be alarming. Altogether, to sum up with regard to safety and ease of procedure, there must be preparation and aseptic technique as for abdominal section; the actual inflation was exceedingly easy; the procedure was often very unpleasant for the patient, and not free from rather remote risks of very considerable pain and distress. Any undesirable effects appeared to be usually quite transient. Several deaths had, however, been reported.

With regard to the scope and limitations of the procedure, the speaker said that children usually bore it better than adults. Debility and cachexia, unless extreme, did not form a contraindication, but all inflammation of the peritoneum which showed any sort of activity, whether recent or not, should be approached with caution, and recent lesions of the peritoneum, whether primarily acute or subacute, were an absolute contraindication, owing to the possibility of separating recent adhesions or of generalizing a local infection. All conditions associated with alteration in size, shape, or contour of the liver, spleen, kidneys, uterus, and ovaries were suitable. The method was useful for abdominal tumours, other than those of the alimentary tract, the latter being demonstrated better by the opaque meal and enema. A certain number of gall stones which could not be shown on ordinary examination were demonstrable by pneumoperitoneum, but he had not met with much success in this direction. With regard to urinary calculi, the percentage of cases in which these could not be shown by ordinary examination with proper technique was exceedingly small. The degree of accuracy in diagnosis attainable by this method varied with the type of lesion. He had had most success in deciding as to the presence or absence of adhesions and the relations of tumours to the solid viscera. The nature of the tumours had eluded him. There was every reason, however, to think that with wider experience it should be possible to make a much larger percentage of absolutely definite diagnoses.

Finally, he spoke of the value of this method as compared with others. For pneumoperitoneum radiography to attain a high place in the regard of the profession, it must be insisted that only carefully selected cases be submitted to this procedure, and that the process of selection should involve thorough clinical examination, with any special examination which might be indicated. He deprecated inflation as a routine method for every subject with symptoms which might (or might not) have their origin in the abdomen. In carefully selected cases the method would very frequently furnish information which could not be obtained by any means short of exploratory laparotomy.

Dr. WOODBURN MORISON (Manchester) agreed that the operation of gas inflation was a definite surgical process; if that were generally accepted, then it was a surgeon's work. A medical man with surgical qualifications, of course, could practise as he chose, but in Manchester it was not desired that the surgeons should invade the sphere of the radiologists. In that city they had done about one hundred such operations; he had never been able to show gall stones by the method unless they had been previously demonstrated with the ordinary plate, and he agreed with Dr. Herniman-Johnson that if the stones were of sufficient density to give a good picture they could be shown by the ordinary plate examination.

The PRESIDENT said that this was one of the newer methods in x-ray practice, and the Section was under an obligation to Dr. Herniman-Johnson and Dr. Redding for their valuable contributions. They were pioneers in a new method, which, like every new method, was open to exaggeration and abuse. What he himself wished to know was why the presence of air made a part peculiarly transparent to the rays.

Dr. HERNIMAN-JOHNSON, in reply, said that the operation itself, if skilfully done, hurt the patient no more than the anaesthetizing of the track of the needle would do. In his opinion CO_2 was much more desirable than oxygen, but with CO_2 as the distension disappeared in about three-quarters of an hour, it was necessary to be fairly speedy in making the exposure; that was the only disadvantage of this gas as compared with oxygen. To relieve the discomfort after operation he had found one-sixth of a grain of morphine very useful. It was advisable to keep the patient supine for some time. Puncturing of the spleen should not take place if care were exercised. He agreed that the method often failed in the diagnosis of gall-bladder calculus. With regard to a point as to technique raised by Dr. Morison, those who had been general practitioners could not realize, and probably never would realize, why they should not use needles in the same way as they had been accustomed to use them in general practice. Possibly a new generation of radiologists, who had been brought up, after graduation, to x-ray work alone, might find a difficulty. Too narrow a specialism was to be deprecated. Surgeons quite rightly made use of x rays and electricity when they considered it advantageous to their practices, and a similar liberty should be given to other experts. One thing at least was certain: had Dr. Morison's views met with general acceptance in the past there would be no discussion on peritoneal inflation to-day, as the method had been initiated by radiologists, just as diathermic surgery owed its beginnings to electro-theraputists. With regard to the usefulness of injected gas in showing up organs, it acted chiefly by pushing the parts away from each other, but there might also be some refractive effect as yet not fully understood.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE DIMPLE ON THE CONDYLE OF THE FEMUR.

THERE is a little dimple or depression, situated just above the popliteal groove, on the outer condyles of the great majority of femora. This dimple is entirely ignored by most textbooks of anatomy, and in the few instances in which it is alluded to it is said to be caused by the pressure of a sesamoid bone which is sometimes present in the outer head of the gastrocnemius.

A short time ago, while acting as demonstrator in the Anatomy Department of Glasgow University, I investigated this matter, with the help of Dr. D. M. Blair, the senior demonstrator. We examined between us a dozen lower limbs; we found that no sesamoid bone was present in seven out of the twelve specimens; but in spite of this fact the suprapopliteal depression was well marked in each case. In the remaining five specimens a sesamoid bone or cartilage was found; but in no case did it correspond in position to the depression, being always at least half an inch below and lateral to it.

Some other explanation will therefore have to be found for the existence of this peculiar dimple. So far as we could see, it had absolutely no *raison d'être*—nothing originated from it, nothing occupied it.

UNSUSPECTED PREGNANCY.

I think I ought to record an experience I had about twenty years ago, because of its medico-legal significance.

I was summoned at the last minute to attend a confinement. After the birth of the child, a healthy male, the mother made the following statement: She had been married over eight years, and had been regular each month. Her last period finished two or three days before this unexpected birth. Her figure had not changed in the least; she wore the same stays and dresses throughout with no adjustments or alterations. A short time before delivery she had a little stomach ache, which she ascribed to having eaten a supper. The child was born as the result of one long pain only, and the process was a matter of a few minutes only. The medical attendance merely consisted in division of cord and application of a binder. The husband had no suspicion of his wife being pregnant, and was quite excited and flustered at the unexpected birth.

I also questioned a married woman who had had several children, and who occupied part of the same house. She had not noticed any sign of pregnancy in her friend, neither in figure, dress, nor anything else.

The whole set of circumstances seems almost unbelievable, but I closely questioned all parties concerned at considerable length, and as there was no conceivable reason for speaking anything but the truth I unhesitatingly accepted the statements as facts. I still believe these things to be true in every particular.

London, S.W.

JOHN FLETCHER.

A DIPHTHERIA CARRIER.

Miss E. R., aged 28, of robust appearance, had been found to be a carrier of virulent diphtheria bacilli in November, 1921, when an outbreak occurred in a school where she was matron. An autogenous vaccine prepared at Manchester University and also a stock vaccine were administered without effect, as follows:

Three doses of autogenous vaccine, each containing 10 million bacilli, were injected—one each on January 20th, January 27th, and February 3rd; three doses of the stock vaccine were also injected—one of 25 million on February 28th, one of 50 million on March 6th, and one of 25 million on March 17th. Swabs taken on various dates subsequent to the commencement of the injections showed, on culture, the following results:

February 2	...	swab +	March 4	...	swab +
" 8	...	" -	" 16	...	" +
" 18	...	" +	" 22	...	" -
" 25	...	" -	" 28	...	" +

After the dose of 50 million stock vaccine (undetoxicated) there was considerable reaction, and the patient complained of very distressing pain in the region of the heart with a feeling of oppression, but there was no tachycardia, dilatation, or valvular disease. These symptoms had not been present before the use of the vaccine; in fact, the patient had felt perfectly fit. She refused further injections after March 17th.

On March 14th I removed the right tonsil, which was somewhat hypertrophied; the left tonsil was only visible on retraction of the anterior pillar of the fauces. As diphtheria bacilli were still present on March 28th I sent her to Dr. E. H. R. Harries, who reported numerous diphtheria bacilli on the left tonsil and a few from the nose, and recommended dissection out of the left tonsil; this was done by Mr. A. L. Yates on April 21st, and he removed some adenoid tissue at the same time. Swabs taken subsequently showed the following results:

May 10	...	swab +	May 24	...	swab -
" 17	...	" -	" 30	...	" -

On May 10th a slough was still present in the nasopharynx; after this had separated the swabs were negative. Local treatment after removal of the tonsils consisted of swabbing over the tonsil beds and nasopharynx daily with 10 per cent. argyrol, except on mornings before swabs were taken.

I think this case only emphasizes the uselessness and even harmfulness of vaccines for these cases, and the necessity for thorough removal of any unhealthy tissue, without which the diphtheria bacilli cannot be dislodged.

Rebickus.

CANCER OF THE BREAST.

MR. HANDLEY published the first edition of his book on *Cancer of the Breast* in 1906, and it says much for the thoroughness and care with which his original investigation was conducted that in this, the second, edition,¹ published sixteen years later, there has been need for practically no alteration of any consequence in that section which deals with his pathological work.

The arrangement of the contents of the volume is based on a scientific principle which ought to be more frequently followed. The book begins with a detailed statement of the evidence on which Mr. Handley relies to establish his theory of the way in which carcinoma of the breast is disseminated; later chapters treat of the process of repair in carcinoma, the normal anatomy of the breast, the treatment, operative, by x-rays, and by radium, and of recurrence. Paget's disease and the dissemination of melanotic sarcoma are discussed in two interesting and illuminating chapters.

The two sections of the book which will probably first attract attention are, curiously enough, neither of them strictly concerned with the main thesis of the volume. Chapter X deals with the anatomy of the breast and its lymphatic glands; here we confess to some feeling of disappointment; in a volume of such excellence and importance place might have been found for a more detailed account of what must essentially form the groundwork of successful pathological investigation. In contrast to this, the chapter dealing with the radiological treatment of carcinoma is one of the best presentations of the subject which we have read. It puts the highly important question in an exceedingly fair light, and we would commend its perusal to all who have anything to do with the radiological treatment of carcinoma. We have only one criticism to make: it would, we think, have been well to have recounted in greater detail the work of Murphy and Rous and their collaborators; Mr. Handley dismisses their investigations very briefly and does not even mention their names; but their results are, we believe, generally considered to be of great significance.

The first chapter deals with the inadequacy of the embolic theory of the dissemination of carcinoma; Mr. Handley is strongly in favour of the view that breast cancer is disseminated by the lymphatic vessels. While he does not deny the possibility of cancer cells entering the blood stream, he believes (and his belief is mainly based on the work of M. B. Schmidt) that the blood exerts so strong a destructive action upon the cancer cells that bacemic embolic metastasis is an extremely rare occurrence. Recent experimental work tends to call in question some of Schmidt's results, and we suggest that the papers Czorny published in 1913-14 are of interest in this connexion. With great originality a mass of evidence is presented in favour of the view that the disease is disseminated by way of the lymphatics along the deep cervical fascia. The author draws a clear distinction between spread by infiltration and spread by permeation; the latter is the advanced guard of the disease, and by ingenious argument, if not by demonstration, Mr. Handley shows that it is along the smaller lymphatic vessels that the cancer cells primarily extend.

There are not many who will express disagreement with his views, but to a critical mind the demonstration is not so convincing as Mr. Handley would have us believe. Naked-eye evidence, as shown by the skin nodules, is untrustworthy; such evidence can only be obtained in the advanced stages of the disease, and the nodules, therefore, are no criterion of an early process. Microscopical evidence will be convincing when the process, as Mr. Handley describes it, can be demonstrated in a complete series of serial sections. The labour would be enormous, and the observer to undertake it has yet to appear. The examination of a single strip, or even of two radial strips, is not sufficient evidence of what may be occurring in other planes and serials. The author describes his conception of the disease and its spread as being that of a biconvex lens, by which description we may infer that he believes that the dissemination of the disease, while not necessarily circular, is yet radially uniform from a common centre. It is difficult to reconcile this exact conception with

¹ *Cancer of the Breast and its Treatment*. By W. Sampson Handley, M.S., M.D. Lond., F.R.C.S. Eng. Second edition. London: Published for the Middlesex Hospital Press by John Murray. 1922. (Med. 8vo, pp 411; 82 figures. 30s. net.)

what happens in cases of epigastric abdominal involvement. Is it not more natural to assume that there has been a lymphatic dissemination of the disease along one definite line?

There is difficulty also in agreeing with Mr. Handley in his dismissal of the blood route of infection. In those cases which show secondary deposits in the dura further evidence seems to be required to carry conviction that such deposits are explained by a lymphatic dissemination along the deep fascia extending as far as the scalp, and yet giving rise to no other superficial manifestation.

A very interesting and encouraging portion of the book is that which deals with the natural tendency to cure in carcinoma. It is encouraging because we are too apt to be pessimistic where malignant disease is concerned; here again, however, we cannot help wishing that Mr. Handley could show us more convincing evidence of the radial fibrotic cure which he so dramatically describes.

In the section which deals with the principles of the operation for breast cancer we are glad to call attention to the importance Mr. Handley attaches to the too often neglected rule that the primary growth shall always be the central point of the mass of tissue which is cut out in order to remove cancer. Too often the rule is broken in order to ensure a more adaptable scar. We do not find that Mr. Handley has expressed an opinion on the question whether the axillary dissection should precede the removal of the breast and its associated parts. There are many who believe that to introduce the operation by an axillary dissection is a great material advantage. We hope we shall not be accused of levity if we allude to one point which must interest all who play golf—and in these days who does not? In January, 1912, Mr. Handley carried out the radical operation for breast cancer on a lady who, within six months of the operation, defeated her husband, a scratch player, though she was in receipt of only three strokes! Golfing stories, like fishing stories, are always refreshing, and this is one of the best we have heard.

But, apart from these criticisms, golfing and otherwise, we have nothing but admiration for this most excellent volume. The research has been conducted in a most scientific spirit, there is evidence throughout of admirable care and attention to detail, and if on occasion the reader has the feeling that the cloth has been cut to suit the tailor, one must remember that it is a fault to which every original investigator is liable. In future editions we hope that Mr. Handley will give us the benefit of his great experience by recounting further problems of breast pathology in relation to other tumours.

THE PATHOLOGY OF LETHARGIC ENCEPHALITIS.

PROFESSOR TAROZZI'S monograph on non-suppurative encephalitis and so-called lethargic encephalitis² is based on observations made on cases during the epidemic at Modena between December, 1919, and January, 1920. The book is mainly devoted to the anatomical, histological, and bacteriological study of the disease, together with an account of the author's experiments on animals. The anatomical and histological observations are divided into three groups. The first comprises those cases which showed symptoms of epidemic encephalitis during life, the diagnosis being confirmed by *post-mortem* examination; the second group consists of cases which came to autopsy with the diagnosis of influenza or acute bronchopneumonia with or without symptoms of cerebral involvement; and the third group consists of miscellaneous diseases. All the eight cases of the first group with one exception showed diffuse lesions of the bronchopulmonary system referable to influenza, and the parenchymatous organs showed degenerative changes due to toxic infection. The lesions in the central nervous system both on naked-eye and microscopic examination presented the appearances characteristic of epidemic encephalitis. Bacteriological examination of the cerebro-spinal fluid was always negative. In six of the twelve cases belonging to the second group a study of the central nervous system showed lesions similar to those found in a more marked degree in encephalitis. In the third group, which comprised eleven examples of various diseases such as tuberculosis, pemphigus, purpura, nephritis, and carcinoma of the pancreas, histological lesions resembling those of encephalitis were found apart from any clinical signs of nervous involvement. The experimental work performed by the author consisted of inoculation

of rabbits with pure cultures of diplostreptococci obtained from bronchopneumonic areas in cases of encephalitis. The inoculations were made beneath the dura mater, into the cerebral substance, into the carotid, jugular vein, and peritoneum; the lesions produced were similar to those met with in lethargic encephalitis.

Professor Tarozzi maintains that the anatomical and histological changes of so-called lethargic encephalitis do not differ in any respect from those found in non-suppurative encephalitis, and especially from the encephalitis which may accompany influenza. *Post-mortem* examination of cases of encephalitis always shows the changes in the respiratory tract usually found in influenzal bronchopneumonia. Moreover, in the central nervous system of persons who have died of influenza lesions are found in a marked degree with relatively greater frequency in those who have presented clinical symptoms of encephalitis during life. The histological changes in the central nervous system in lethargic encephalitis are presumably to be attributed to the local action of circulating toxins produced by the diplostreptococci which are responsible for the inflammation in the respiratory tract. There is, thus, the author concludes, a close causal relationship between influenza and encephalitis. The hypothesis that influenza merely predisposes to infection of lethargic encephalitis is dismissed as inadequate.

THE POPULATION PROBLEM.

Discussion of the population problem generally excites as violent animosities as debates on psycho-analysis, no doubt because both topics are more or less concerned with a taboo. The fury aroused by Parson Malthus lives in Cobbett's pages, while the more genial satire of Peacock can never lack admirers. Lord Morley tells how Mr. Gladstone withdrew from co-operation with the promoters of a memorial to John Stuart Mill because of a doubt whether Mill had not advocated obnoxious checks to population. Eminent statisticians, even correspondents of the *BRITISH MEDICAL JOURNAL*, have been a trifle fierce on the theme. Mr. CARR-SAUNDERS³ possesses the distinction of having devoted a volume of more than 500 pages to this exciting subject without a single lapse from academic decorum and without giving the most sensitive reader cause for anger. He has diligently perused a large number of books and memoirs (his bibliography includes about 1,000 titles) and has attempted to sum up the whole case in the manner of a judge. He has achieved a fair measure of success, although the field he essays to cover is so wide that specialists will no doubt find errors. Actuaries, for instance, will object that neither Macdonell's deductions from the *Corpus Inscriptionum Latinarum* nor the rates of mortality in Price's Northampton Table give any information about that terribly mishandled function, the "Expectation of Life," either in ancient Rome or eighteenth-century England, because the method of calculation was unsound. But not even a diligent Oxonian can be equally well informed on all points. The general reader is likely to be awestruck by the range of Mr. Carr-Saunders's erudition. The harshest criticism such a reader is likely to make is to recall some sentences of Bagehot: "There is as much variety of pluck in writing across a sheet as in ric"
Cautious men have many adverbs—
safe men begin, 'it may be ai.
Saunders is cautious and safe, although he has courage enough to dissent from opinions very influentially supported. Perhaps we can best give an idea of the qualities of the book by quoting the concluding passage.

"On the other hand, those who think that germinal change in mental characters will affect the evolution of society and mould the course of history are upon the whole mistaken. The course of history is in the main dependent upon changes in tradition which are for the most part independent of germinal change. Just as the outstanding happenings in the last century—the turning of thought and conduct in Germany, for example, along certain lines, which ended in so great a catastrophe—were due to changes in tradition and not to changes in the germinal constitution, so whether the problems now pressing upon European society are to be solved, or whether some greater catastrophe, reaching a climax in a long course of years or bursting suddenly upon us, is to be the outcome, will depend upon changes in tradition and not upon germinal change. The reason for this lies in the fact that the vast accumulation of tradition overlays the outward expression of mental character, determines the direction of intellectual activity and moulds the expression of the instinctive faculties. But as far as tradition is equalized, so far do innate mental

² Sulla encefalite non-suppurativa e la cosiddetta encefalite letargica. By Professor Giulio Tarozzi. Modena: Società Tipografica Soliani. 1921. (Med. 4to, pp. 99; 6 figures.)

³ The Population Problem: A Study in Human Evolution. By A. M. Carr-Saunders. Oxford: Clarendon Press. 1922. (Med. 8vo, pp. 516; 21s. net.)

differences manifest themselves as between man and man, and since tradition is more or less equalized, if not within races, at least within classes in the same race, to that degree is mental endowment of pre-eminent importance to the individual."

At first this seems rather bold, a challenge to those who believe Nature more important than Nurture. But when one rereads it, perpend the final sentence, and remarks that Mr. Carr-Saunders defines tradition (on p. 409) as the "product of conceptual thought," one comes to doubt whether it really is so very bold after all. The character of the product must, we should suppose, depend upon what "conceives" it, therefore ultimately tradition *does* depend upon "germinal change." Perhaps the very bad tradition of Germany was a consequence of the conditions of selection a generation ago, which Mr. Carr-Saunders allows (on p. 464) to have played some part—his cautious words are, "may have played a minor part."

In fact, Mr. Carr-Saunders's caveat against the eugenists is a very mild one indeed. Perhaps all it really amounts to is this. When, as in Rome, a small number of highly intelligent and cultivated persons was surrounded by a vast population of entirely uncultivated and quasi-barbarous persons, the mutual destruction of the intelligent minority led to chaos; there was no sufficient tradition—using the word in a slightly different sense from that of Mr. Carr-Saunders—to keep the machine working. In a modern State this could not happen. If every educated Englishman were shot to-morrow the means of knowledge are so widely disseminated that, within a few generations at most, there would be a recovery to the original position.

Upon the narrower issues, the question of checks to population and the determination of the optimum population, Mr. Carr-Saunders is again a cautious but not inspiring guide. It may be a bold thing to say of any book on the population question, but we will predict that this work will not excite violent controversy.

X-RAY DOSAGE.

The Principles of Physics and Biology of Radiation Therapy is an English translation of Krönig and Friedrich's book made by Dr. Henry Schmitz, Professor of Gynaecology at the Loyola University School of Medicine, Chicago. The original German edition was published in 1918, but the translation has been brought up to date by the addition of accounts of various investigations made by Friedrich and his assistants since that date; this, the translator states, has been done in order to demonstrate the important bearing of the original work upon the progress and development of radiation therapy.

Some idea of the comprehensive character of this publication can be gathered from the material which constitutes the two main portions. Part I, dealing with the physical principles of radiation therapy, is largely concerned with the question of dosimeters, and an instrument is described which appears to conform to all the demands of radiotherapy; there is a unit of dose and a method to gauge the scale of the dosimeter based upon this unit. The experiments made in order to perfect the iontoquantimeter are described in detail, together with errors of construction which have to be guarded against. An extraordinary number of experiments are detailed in this part of the book, ranging from those concerning the reliability or otherwise of Kienböck strips, the Sabouraud pastille, and the Fürstenau intensimeter, to those carried out in order to make a comparison between the depth dose calculated from the surface dose and the depth dose measured in the water phantom, and also experiments carried out with α rays filtered through 1 mm. of copper at different depths and with different sized fields. The number of tables of these various results is somewhat bewildering to a reader who is not an expert physicist.

The second part is occupied with the biological principles of radiation therapy, and is in effect an attempt, with the aid of the measuring methods described in the first part, to define the laws which govern the action of α rays and of radio-active substances on biological objects. Realizing that laws could not be framed without much preliminary investigation on the lower forms of animal and vegetable organisms, a large number of experiments were first of all made on frog larvae, and these are the subject of the opening chapters of this section.

Having convinced themselves that definite laws for the

biological action of the various types of α ray could be founded on these experiments, the authors in the following chapter deal with their investigations made on human tissues; the three tissues chosen are the skin, carcinomata, and the ovary. Detailed accounts of experimental work on these three tissues, chiefly of the action of α rays through filters of 3 mm. aluminium or 1 mm. copper, occupy succeeding pages, and comparisons are made with the biological action of the gamma rays of both radium and mesothorium. All this part of the work is of the greatest interest and importance to the radiotherapist, and its arrangement is such that it is easily followed and understood. In each experiment the aim is first of all stated, then a short account of the details of the actual experiment is given, together with, in some cases, the control observations; finally the results and their bearing on the subject are summarized. This part concludes with an account of the methods of arriving at the sensibility quotient for the ovary and for carcinoma, and notes on the dependence of the intensity of the biological action on the same dose.

With regard to the main conclusions which are the outcome of all this work, it is definitely laid down that the average erythema dose can be, and is, determined; but that at the same time undersensibility as well as oversensibility can be proved to exist: the former, pronounced undersensibility, is frequently observed in very old, decrepit, and markedly cachectic individuals, even up to the amount of 100 per cent. The conclusion as to the ovary is that if the dose recommended to produce amenorrhoea is administered the age of the patient is practically of no importance—the successful result must follow on the dose. In carcinoma in some cases a tumour would completely disappear to the senses of sight and touch, whilst in other cases the tumour was refractory in spite of the same α -ray dose. The reasons for the great individual differences in this respect are unknown.

It is impossible to do more than give a general impression of the scope and the value of the experimental work detailed with so much care and exactness. The value of the book to the radiologist and especially to the therapist is obvious; it is well got up, printed in excellent type with large margin, and the illustrations, chiefly diagrammatic, are very good.

NOTES ON BOOKS.

The Handbook of Tuberculosis Schemes for Great Britain and Ireland, edited by the National Association for the Prevention of Tuberculosis,⁵ which has now reached its third edition, is a mine of useful information. Collected within its pages are facts and statistics which could only be obtained by the individual after an altogether unreasonable period of reference hunting. Classified in an admirable manner, and reproduced in the minimum of space consistent with clarity, are lists of all the tuberculosis schemes for the British Isles, together with the area, population, industrial occupation, and death rates from all causes—and from tuberculosis in particular—of each district concerned. In ten charts are given the death rates from tuberculosis—pulmonary and other forms—for 1920 in Great Britain, the age and sex distribution for the last sixty years, and the fall in the death rate for the same period. The information in regard to Ireland is somewhat meagre, but the figures alone are sufficient to indicate the backward state of that country in relation to tuberculosis administration. A tabulated plan of schemes laid out for counties and county boroughs, and a complete list of residential institutions—both official and voluntary—for the treatment of tuberculosis, giving the number of available beds and the class of case to which admission is restricted, conclude the book. We have no hesitation in recommending it to all who are interested in the progress of the campaign against tuberculosis in this country. As a handbook for the information which it is intended to supply it will prove invaluable.

Dr. FERDINAND HUEPPE, of the German University of Prague, has edited a second edition of his book on physical training.⁶ This is concerned largely with training for sport, and the author goes into the subject fully from both the physiological and practical sides. The book is illustrated by a number of reproductions of photographs of Greek statues and modern athletes, and discusses the various types such persons may present.

SOME PROPRIETARY VITAMIN PREPARATIONS.

THE literature about accessory food factors grows apace, and not only are newspaper readers becoming familiar with the idea of vitamins, but the attention of manufacturers of foods and drugs has been attracted, and some of them have sought to turn the idea to commercial purposes in a manner which must be pronounced to be at least premature. To preserve foods so that the vitamins they contain when fresh are not destroyed is difficult; to obtain vitamins in concentrated form must therefore be still more difficult. The enterprise of manufacturers is being displayed on both sides of the Atlantic, and the *Journal of the American Medical Association* recently contained two articles giving the results of independent scientific experiments made to measure the vitamin content of certain proprietary articles advertised as containing vitamins. Not all the articles studied are known on this side of the Atlantic, but the principle involved is of general interest, and we therefore propose to give a short account of certain results obtained by investigations carried out in the departments of pediatrics and pathology of the University of Illinois College of Medicine, Chicago, and in the department of chemical hygiene and public health of Johns Hopkins University.

Vitamin C, it will be remembered, is antiscorbutic, and vitamin B is generally spoken of as the antineuritic or anti-beri-beri vitamin. Drs. Julius H. Hess, J. J. Moore, and J. K. Calvin,¹ at Chicago, measured the amount of vitamin C and vitamin B contained in certain preparations advertised in America; the preparations examined included "Metagen" (Parke Davis), "Mastin's vitamons tablets," and "Yeast Vitamine-Harris"; in the last preparation only the vitamin B content was measured. They concluded that "Metagen as obtained on the open market contains no demonstrable amount of antiscorbutic substances, as shown by experiments on the guinea-pigs. The effect of the ageing of this product after leaving the manufacturing laboratory may be of importance." They found that Metagen contained vitamin B, but that it was less efficacious than fresh yeast in preventing and curing polyneuritis in pigeons. "Yeast Vitamine-Harris" contained nearly as much vitamin B as did fresh yeast, while "Vitamon" contained only a small amount of vitamin B. Neither of the last two preparations contained appreciable quantities of vitamin C. Their final conclusion was: "It appears from the foregoing experiments that the process of manufacture and subsequent ageing of the concentrated vitamin products have not caused as much deterioration of the antineuritic as of the antiscorbutic properties. All the products studied were very low in antiscorbutic properties, and while all of them contained water-soluble B, they had a much lower potency than fresh yeast, with the possible exception of the Yeast Vitamine-Harris preparation."

McCollum and Simmonds² examined six products—Mastin's yeast vitamins tablets, "Yeast Vitamine-Harris," "Double Strength" yeast and iron concentrate, Irving's Phospho vitamins, Alpha vitamins tablets, and "Super-vitamin" tablets. They tested these products for the presence of vitamin B, which is the most stable of the three vitamins, and therefore the one most likely to survive the processes of manufacture. From the dose recommended by the manufacturers for an adult they calculated the proportional dose required by a rat, and then tested these products by giving twenty times the calculated dose to young rats kept on a vitamin B free diet. The presence or absence of vitamin B in the preparations was indicated by the presence or absence of growth in the rats. Five of the products tested were found to contain, at the most, only traces of vitamin B, whilst the sixth preparation, "Yeast Vitamine-Harris," contained a moderate quantity of vitamin B.

These results confirm the expectations of all who have worked with vitamins. These bodies are very unstable, and hitherto it has been found practically impossible to concentrate them in the laboratory. Vitamin C is rapidly destroyed by any chemical treatment. All attempts to concentrate vitamin A have hitherto failed, and it is extremely difficult to concentrate vitamin B, although this is the most stable of all the three vitamins. Hence it would be very surprising if any manufacturer had succeeded in producing concentrated vitamins in a stable form on a commercial scale. The experiments quoted show, in fact, that some of the preparations tested are practically free from vitamins, and that the others contain less vitamin than ordinary yeast. McCollum, in his article, points out that a well-planned diet will afford an abundance of vitamins, and that there is no evidence that an excess of vitamins can produce any beneficial therapeutic effect; hence, even if the production of concentrated vitamins in a stable form were found to be a possible commercial undertaking, there is at present no evidence to show that such preparations would be of any definite therapeutic value. But, as McCollum says, "There prevails in the minds of most people, however, a childlike confidence that these substances [vitamins] must have a medicinal value." After pointing out that some manufacturers are offering for sale "extracts which purport to supply vitamins in concentrated form," he continues: "The extensive advertising of such nostrums, and the reports of druggists as to the extent of the demand for these products, leave no room for doubt that there is a great demand for them, and at fancy prices."

McCollum is fully alive to the fact that a human being can only thrive when fed on a diet containing a sufficient supply of vitamins, and observes that the concentration of populations in towns has resulted in our diet consisting essentially of highly milled cereal products, muscle meats, potatoes, and sugar. Such diets are insufficient to maintain animals in health and are proving a failure in the case of children. Such diets should be supplemented by vitamin-rich foods, of which the most important are milk and milk products, green vegetables, and fruit—substances which McCollum designates as "protective" foods. He advises that a diet should include salads twice a day, a liberal helping of cooked green vegetables once a day, and the equivalent of a quart of milk as milk or milk products.

If these statements are to be accepted as representing the approximate quantities of protective foods required to maintain full health, and we are not disposed to quarrel with them, it is obvious that the great majority of our urban populations are living on a diet deficient in vitamins. This deficiency is to be remedied by dietary reform.

THE EPIDEMICS OF EASTERN EUROPE.

WE have received a copy of a new pamphlet, *Epidemiological Intelligence*, No. 3, published by the Health Section of the League of Nations,* relating to the epidemic situation in Russia and Eastern Europe. This is a continuation of previous pamphlets on the subject, and it supplements the shorter bulletins which are now furnished to the public health departments of different countries about every ten days. It contains an analysis of the reports of the several national delegations to the European Health Conference at Warsaw which was held in March of this year, and a summary of the present state of health defence in the European sanitary zone. Contact between the Health Section of the League and its Epidemic Commission on the one hand and the Russian health authorities on the other was established in September, 1921, and has since been maintained and extended. The "People's Health Commissariat" of Soviet Russia places at the disposal of the Health Section facilities for collecting epidemiological intelligence, and all kinds of Russian publications are supplied regularly to Geneva.

From the information contained in this document and associated bulletins it is only too obvious that the epidemic situation in Russia and the border States continues to be very grave. Typhus and relapsing fever are stated to have been responsible for at least two million cases officially reported during the first five months of the year. The seasonal fall in typhus incidence at the end of last winter was not very pronounced in Russia as a whole. The number of cases is said to remain actually at the winter level in the Ukraine. The case mortality from this disease is estimated to be considerably higher than the average of the last three years. New centres of cholera are also being discovered in Russia and the Ukraine, seventy provinces now being involved to greater or less degree. The disease has spread mainly along railway lines, and to a large extent has been carried by railway employees and also by refugees. It has not so far assumed the proportions of last year's extensive outbreak; the most remarkable epidemiological feature is perhaps the continuous character of its progress. It seems that preventive vaccination has been carried out on a large scale in certain parts of Russia. Cholera has not spread extensively beyond the frontiers of the Soviet territories, but there have been several cases at the Polish quarantine station at Rovno, and one or two are reported farther west traceable to direct contact from this station.

The Health Committee of the League of Nations, at its recent August sitting in Geneva, received this report and the report of the special Epidemic Commission of the League which has been working in the frontier areas for the last two years. The Committee decided to direct the immediate attention of the Council (now in session) to the following considerations in order that all practicable action may be taken without delay: (a) "The Committee has no reason to modify the estimate of the gravity of the situation in Eastern Europe in regard to the spread of typhus, relapsing fever, cholera, and other epidemic diseases which it expressed in May last." (b) "The way in which international measures can be applied so as to combat these diseases successfully is well known. The benefit of such measures is incontestable. The experience of the Health Organization and of its Epidemic Commission is available. In short, the field for successful international effort is limited only by the question of the money and material which can be secured." (c) "As a practical matter, it is essential to have a programme for immediate action limited as strictly as possible to the most urgent necessities. In the opinion of the Committee, the work of the Epidemic

Commission during the winter 1922-23 should primarily be concentrated within a zone which includes the States bordering Soviet Russia and the Ukraine on the west, together with a defined portion of Soviet Russia and the Ukraine itself. Within this area the advantages to be derived from international effort are greatest and the need most urgent, and this work should be carried out by enabling the Epidemic Commission to continue and develop its work on the lines which it has so successfully followed during the last two years. Attention is also needed to the prevention of the spread of cholera from Black Sea ports." (d) "The invaluable work of the Epidemic Commission has been carried out by means of a total sum of about £200,000, now practically exhausted. New funds must be found at once to carry out the limited programme outlined above. The Health Committee begs the Council to use all its efforts to obtain fresh funds for the purpose at the earliest possible date."

The British Government, we understand, has already promised a contribution of £100,000 (or less amounts in proportion) for the continuance of this work, subject to the condition that £100,000 is forthcoming from the other nations contributing. The great importance to all Western European nations of the maintenance and enlargement of the sanitary zone on the borders of Russia, whilst that country and the Ukraine remain so huge a source of infection, and especially whilst repatriation is still incomplete, will be obvious to all who read this latest pamphlet. The work done by the Epidemic Commission has evidently been of the greatest value. It represents a co-ordination of effort which no other organization could at present attempt to supply, and we wish the Health Committee and the League every success in their attempts to stir the nations to work, not only of the highest humanitarian value, but vitally important in their own defence.

Space does not permit us to do more than draw attention to many interesting epidemiological features in this pamphlet, such as the peculiar alternation between the epidemics of scarlet fever and typhus fever in Rumania, and the strange variations in virulence as shown by case mortality rates in several of the diseases. We note that it contains also a useful summary of influenza mortality in European cities. This might with advantage be published separately from the epidemic diseases of Eastern Europe; it would be particularly appropriate as a contribution to the *Bulletin of the Office International d'Hygiène Publique*, which is already a mine of information on the occurrence and type of influenza throughout the recent pandemic.

THE SENSE OF SMELL.

THE possession of a sense of smell is one of our natural gifts, but the possession of any knowledge concerning that sense belongs to few. Owing to the inherent and obvious difficulties of the matter investigations have been relatively scanty. Yet the literature of neglected subjects such as this is, none the less, not barren. Various attempts have been made to classify odours and to explain the mechanism by which they reach our consciousness. Of classifications of smells the simplest, and that which will most appeal to the average man, is that of Haller, who in 1763 made them into three classes—agreeable smells, intermediate smells, and disagreeable smells. So might Falstaff himself have described smells, and by this rule our public authorities work to this day—to our great profit.

In more recent years valuable contributions have been made by Zwaardemaker,¹ whose work created considerable

¹ *Physiol. des Geruchs*, H. Zwaardemaker, Leipzig, 1893; and *Geruch und Geschmack*, Handb. der physiol. Methodik, Leipzig, 1910, vol. iii.

* Obtainable through Constable and Company, 10, Orange Street, W.C.2.

discussion, and whose olfactomotor, described in our columns many years ago, opened up wider fields for research. In a thesis recently presented to the University of Brussels, A. Heyninx,¹ in a handsome and well-documented quarto, attacks the problem anew. Zwaardemaker had done a service in reducing the somewhat vague sense of smell to something measurable and capable of clinical application. He had classified odoriferous bodies identical or similar intramolecular groupings are found. But the chemical formulae may vary greatly, and yet a similar smell result—for example, hydrocyanic acid and nitrobenzol have the same odour of bitter almonds.

Heyninx attempts to put the olfactory sense upon a rigid physical basis. In the first place, he laments that we can only speak of smells by periphrasis—by comparing a given smell with that emitted by some well-known object. Before the discovery of the monochromatic elements of the solar spectrum it was by such roundabout means that colours were designated. Indeed, Heyninx wishes to set up a spectrum, as it were, for smell with a classification dependent on variations in the wave-length. By ingenious and closely reasoned argument, betraying considerable knowledge of physical chemistry, Heyninx arrives at the conclusion that the activating mechanism of odours is by the vibration of wave-lengths, the same as those of the ultra-violet part of the solar spectrum. He is attracted by Castelli's theory of resonance in vision—the resonance of the retinal pigment granules in response to waves of light. He uses this theory to explain the pigmentation of the olfactory mucous membrane, and finds that the size of the pigment granules corresponds roughly with the wave-length which odorous bodies emit. An important argument in this connexion is contained in a paper by Ogle² on anosmia; he states that albinos, who have no olfactory pigment, have no sense of smell. Heyninx describes his experiments on the excitator mechanism of olfaction; they show that it is not a radio-active energy, nor a chemical, nor a colloidal, nor a spectral absorption, but a molecule-vibratory energy which activates our affective paths.

Dr. Heyninx's contentions are deserving of attention, and his large and extremely well produced book will be found a mine of information with a rich bibliography.

THE GOVERNMENT LABORATORY.

An important though little known department is that of the Government chemist, otherwise known as the Government laboratory. The present establishment consists of the Government chemist and his deputy, with five superintendent chemists, nine chemists class I, twenty-three chemists class II, and thirty-six temporary assistant chemists. A brief sketch of the manifold activities of his department is given by Sir Robert Robertson, K.B.E., D.Sc., F.R.S., in his report for the year ending March 31st, 1922.³ The chemical work of some fourteen Government departments is now done wholly or in part in the laboratory at Clement's Inn Passage. The other laboratory at the London Custom House deals especially with customs samples; but to avoid delay in examination "chemical stations" have been established at the more important seaports, where samples are tested by customs and excise officers who have been trained at the Government laboratory for this purpose. There is also a laboratory at Deptford for the inspection of War Office food stores and supplies. In all, more than 300,000 samples are examined every year. Much extra

work has arisen in connexion with the Safeguarding of Industries Act, the Dangerous Drugs Act, and the Dye Stuffs (Import Regulation) Act. The work undertaken for the Ministry of Agriculture and Fisheries includes the analysis of a great many samples of dairy produce and margarine. Under this heading we note that the amount of fat in various samples of condensed milk ranged from 7.15 to 10.6 per cent., with a corresponding variation in the proportion of non-fatty solids, indicating that one tin might contain half as much again of milk products as another of the same size; minimum limits for condensed milk have, however, not yet been adopted in this country. The work of investigating the degree of pollution of river water and effluents is increasing, and much has been learnt regarding the proportion of toxic constituents in tar extracts and washings. On behalf of the Crown Agents samples of medicines and drugs taken from supplies for various colonies are examined to see whether they conform to specification. A considerable amount of work is done in determining the gravity of beer for the assessment of duty, and many samples of beer are examined for suspected dilution. Of 431 samples of beer and brewing materials investigated for the presence of arsenic, 24 were found to contain arsenic in excess of the limits laid down by the Royal Commission on Arsenical Poisoning. Of 86 samples of matches examined, none contained any evidence of the presence of white phosphorus. For quite other reasons a watchful eye is kept also upon liquer chocolates and other confectionery suspected of containing alcohol; "many, however, contained only highly flavoured cream interiors, the presence of spirit being due to association with the flavouring essence used." Claims for rebate on alcohol used in making medicinal preparations are referred to the Government chemist by the Commissioners of Customs and Excise; also applications for duty-free alcohol for use in manufactures, teaching, and research. Analyses of the intake and output of illicit stills numbered only 29; this must be in sharp contrast with the corresponding work imposed upon the corresponding department in the United States. We note, too, that none of the "non-alcoholic" wines analysed showed more than 2 per cent. of proof spirit. Medicated wines to the number of 33 were examined, but the result is not recorded, and 33 samples of partially fermented grape juice were classed for duty as wines. This department is called upon also to decide whether a wine of doubtful effervescence is to be rated as still or sparkling. The Post Office employs it to safeguard the purity of the materials used in making stamps, and the Board of Trade to keep watch over the lime juice and lemon juice for crews of ships at sea. An immense amount of tea is examined on its arrival in order to ensure that only that which is fit for human food shall pass into the country. Rejected tea is allowed duty free for use in the manufacture of the alkaloid caffeine; in such cases the tea must first be denatured (usually with lime and asafetida) under the supervision of customs and excise officers. The impression given by this report is that the Government laboratory is almost as useful a friend to public health as it is to the public purse.

THE BRITISH RED CROSS SOCIETY.

In a preface to the Second Report of the Joint Council of the Order of St. John of Jerusalem in England and the British Red Cross Society, the chairman, the Hon. Sir Arthur Stanley, states that in pursuance of its policy "to bring home to the minds of men, women, and children throughout the United Kingdom the vital importance of the prevention of disease" the Council has instituted health lectures to women in rural areas; a syllabus of seven lectures was prepared, dealing with such subjects as general physiology, the digestive system, the skin, hygiene of the home and the village, personal health of the family—child, school boy and girl, and father and mother. The scheme was carried out in nine counties, and has been so much appreciated that requests have been received for its extension to over twenty others during the ensuing winter. Certain medical depôts have been established to supply sick-room requisites on loan to poor people unable to buy them

The Joint Council's Emergency Help Committee has done much work during the year under review (ending March 31st, 1922). It was established in December, 1920, to administer an initial grant of £100,000 by the Joint War Finance Committee or relief of sick and disabled ex-service men in distress. The scheme in its working illustrates admirably the great advantages of cordial co-operation between Governmental and voluntary agencies. Gaps exist in the administration of the Ministry of Pensions scheme, and these can within limits be filled from the emergency fund. It has been administered by county directors, who report monthly to headquarters, and notes on the experience so gained are in turn reported and circulated for general guidance. Inquiries showed a unanimous opinion in favour of its continuance in all parts of the country for six months at least; at the end of that time (September 30th) the position will be reviewed. Relief of widows and dependants is, within limits, included in the scheme, and for that object there is co-operation with the Soldiers', Sailors', and Airmen's Families Association and the United Services Fund. Of the work of the Home Service Ambulance Committee we recently gave a full account. It now has 309 ambulances, and the number of patients carried in the year was 53,743. Voluntary workers have rendered valuable service in the skilled removal of patients. Ambulances have been stationed at the Pensions Ministry's hospitals at Shepherd's Bush and Roehampton for transport to and from omnibus and tramway termini, and have carried jointly over 118,000 cases. Charges are made to patients able to pay, and in this way much of the cost has been defrayed. In those districts in which there is a deficit it is made good by voluntary subscriptions. Hospital services by the Council have included, at the request of the Government's Disposal and Liquidation Committee, the classification, display, and sale of surplus medical stores. The civil hospitals made purchases to the value of about £50,000. A report dealing with the work of the provincial hospitals in 1921 is to be published shortly. In April, 1921, an emergency call at twenty-four hours' notice was received by the V.A.D. Department from the Admiralty to post 300 nursing members to the three principal naval hospitals to take the place of naval ratings called away in connexion with a labour strike; the nurses remained on duty for ninety days. The amount spent under the V.A.D. scholarship scheme was over £43,000; the balance remaining is over £9,000. The students still in training number 144. The report deals also with the Stores and the Trained Nurses Departments. The Finance Committee's report shows that bad as the times are such splendid organizations as compose the Joint Council can still make successful appeal to the benevolence of Britain, and indeed in some degree to that of the four quarters of the globe.

PUBLIC HEALTH IN THE MALAY STATES.

The population of the Federated Malay States at the census of 1921 was 1,298,292, as compared with 1,099,781 in 1911 and 678,595 in 1901. There were 5,466 females to every 10,000 males, as compared with 4,302 in 1911, the male population increasing by 18.1 per cent. and the female by 53.4 per cent. The number of births recorded was 36,294, and of deaths 38,077, the rates being 27.81 and 29.18 per mille respectively. The death rate of the four principal towns (Kuala Lumpur, Ipoh, Taiping, and Seremban) is far too high. Infantile mortality and overcrowding are the main causes. The deaths of children under 1 year numbered 6,646, giving an infantile mortality rate of 183 per mille. An Infant Welfare Advisory Board, under the chairmanship of the chief secretary, Mr. W. G. Maxwell, C.M.G., hopes to effect some good. Malaria was as usual the chief cause of sickness and death. The number of deaths recorded from this cause was 17,168—a considerable decrease from the 20,595 deaths in 1920, but still nearly half the total for all diseases. The death rate was 13.16 per mille, as compared with 15.24 in 1920. Malaria, however, is a factor in many deaths attributed to other diseases. The Malaria Advisory Board meets every month, and almost

every district has a Mosquito Destruction Board. Any estate can obtain an anopheline survey free of cost, together with a report and the health officer's recommendations; but antimalarial measures on estates, to be effectual, must be carried out under the direct supervision of the estate medical officer. The District Mosquito Destruction Boards carry out destruction work in the town areas, villages, and kampongs. The central Malaria Advisory Board advises generally, and controls and co-ordinates the work of the district executive boards. Antimalarial work on estates is the duty of the owners of the estates. It is essential that there should be a policy of combined action by contiguous estates in respect of antimalarial measures, and the Malaria Advisory Board is endeavouring to achieve this. Where antimalarial works are carried out under expert supervision upon an estate, and some State land or small holdings ought also to be treated, the Government makes a fair contribution. The antimalarial works at Kuala Lumpur cover 6,600 acres, and were maintained at a cost of 22,126 dols.; the cost of new works was 105,000 dols. The Port Swettenham antimalarial area of 3,100 acres was maintained at a cost of 4,623 dols. At Seremban a drained area of 1,500 acres was maintained at a cost of 8,283 dols. Surveys at Taiping, Kuala Lumpur, Gemas, and Raub were carried out over an area of 2,600 acres. During the year there were in the various hospitals and asylums 166,785 indoor patients, as compared with 120,879 in the preceding year. Outdoor patients numbered 275,783 in 1920. The increase in the number of out-patients and the decrease in the number of in-patients are largely due to the establishment of dispensaries in crowded quarters of towns. The value of narsenobenzol in venereal diseases is recognized by the coolie class, and they are insistent upon treatment by injection. The same drug is used with great success in the treatment of yaws; 8,547 injections were given in Perak, 578 in Selangor, 21,179 in Negri Sembilan, and 903 in Pahang. In Perak 75 cases of small-pox were reported; by energetic action the outbreak was stopped. At the Institute of Medical Research special investigations are in progress into the occurrence of cases of malaria resistant to quinine, and into the value of "cinchona febrifuge" as compared with quinine. The special inquiry, commenced in 1920, into the pathology and treatment of dysentery was continued in 1921. Further investigations were made into melioidosis (pseudo-cholera) and reactions for syphilis. A study of the distribution of anophelines and the seasonal prevalence of species has suggested that the distribution of species may depend on the nature of the food material available in the breeding places—that is, on the algae and other microscopic organisms, and that these in their turn possibly depend on differences in the chemical constituents of the water. The annual reports of the Institute of Medical Research may be obtained free of charge upon application to the Superintendent, Printing Department, Kuala Lumpur.

THE "CREATION" OF "SIBSON'S NOTCH."

If it be true that a prophet is not without honour save in his own country, there is the consolation that he may possibly get undeserved credit in a strange land. This appears to have occurred in connexion with Francis Sibson (1814-1876), physician to St. Mary's Hospital, who wrote much on diseases of the pericardium, especially in Russell Reynolds's *System of Medicine*, but is scarcely remembered by the present generation, except perhaps for the copious reproductions of his observations in the article on "Diseases of the pericardium" by the late Dr. F. T. Roberts in Albutt's *System*. In a recent paper entitled "La question de l'encoche de Sibson," Dr. Germain Blechmann gives an interesting account of the "creation" of the supposed sign "Sibson's notch," which is defined in Dorland's *American Illustrated Medical Dictionary* as "an inward bend of the left upper limit of precordial dulness in acute pericardial effusion." Though not known in this country it appears to be a familiar term in French literature, having in a textbook on

¹ Blechmann, G.: *Rev. de méd.*, 1922; xxxix, 5-18.

cardiological diagnosis published last year even undergone an evolution into "oncocho do Gibson"! The responsibility for the creation of Sibson's notch has been traced by Blechmann to the famous Potain, who in 1887 gave an account of the bun-like dullness characterized by Sibson's notch at the base of the heart in pericardial effusion. The explanation appears to be a mistranslation of Sibson's statement that "the pericardium in fact yields sideways under the pressure of fluid, and encroaches so far on the left lung as to push it backwards, almost out of sight." Indeed, as Dr. Blechmann points out, Sibson's notch is a fiction for two good and sufficient reasons: in the first place because he never described it, and secondly because it does not occur. The tradition of Sibson's notch shows that even in these days authority may exert undue weight, and that percussion, though a century old, still presents difficulties.

THE CAMPAIGN AGAINST VENEREAL DISEASE IN BELGIUM.

A REPORT has recently been issued of the Conference on the Venereal Diseases held in December last in Paris, under the auspices of the League of Red Cross Societies. Most of the important Western and Eastern European countries were represented, and the two volumes in which this Report is published, together with the report of the Northern European Red Cross Conference for Combating Venereal Diseases held in Copenhagen in May, 1921, constitute a fairly comprehensive survey of recent activities directed against the venereal diseases throughout Europe. A perusal of the speeches of the various delegates leaves the impression that in several countries the campaign, as a definitely organized movement, has hardly begun; and as was to be expected, the efficiency of the various organizations appears to be proportional to the cultural level the different European countries have reached. But whether the delegates spoke of actual achievements or pious hopes, all expressed the belief that recent advances in our knowledge of syphilis were so considerable, and the prospects of controlling it and stamping it out now so promising, as to justify a completely new start, with all the forces of a civilized community converging on this one subject. The paper read by Professor Bayet and Professor Malvoz, delegates for Belgium, may be taken as a fair sample of this modern movement. They pointed out that the arsenical group of drugs is capable of reducing the period of greatest infectivity of syphilis from months to weeks, and argued that if this period could be reduced by three-quarters or four-fifths, an equivalent reduction might be made in the number of infectious persons. The programme of the Conseil supérieur d'hygiène de Belgique, adopted in August, 1920, may be said to pivot on this argument, and therapeutic sterilization of infected persons is regarded as the most effective prophylaxis possible. In translating this principle into practice, the Belgian authorities provide arsenical antisypilitic drugs free of charge on request, whether the applicant be poor or not. Another step of far-reaching importance is the inclusion of every practitioner in the campaign; in the past the treatment of syphilis was chiefly in the hands of specialists, and was conducted at hospitals. Now, dispensaries are being opened, the objects of which are to provide the general practitioner with all the aid he needs. He may send his patients to be treated there, or he may use the dispensary only for consultation and diagnosis, keeping treatment in his own hands. Although fulfilling the functions of a diagnostic, therapeutic, and registration centre, these dispensaries are run on the principle that administrative formalities of a deterrent character should interfere with their popularity as little as possible. Other items in the campaign are a scheme of educational propaganda, the constitution of a medical advisory board, and the development of an organization for the care of the victims of syphilis. Only brief reference was made to gonorrhoea in this programme, but doubtless much of the machinery provided for the campaign against syphilis could be adapted to the control of gonorrhoea. Both the Belgian delegates spoke of syphilis as a disease on which modern science has

a stranglehold, and maintained that it is gradually losing its character as a highly infectious disease with cutaneous and mucous manifestations, being rendered comparatively un-infectious by the arsenical drugs. In this connexion they stated that a diminution in the ratio of primary and secondary syphilis to tertiary syphilis could be noted.

GRADUATE INSTRUCTION IN LONDON.

THE further series of post-graduate lectures arranged by the Fellowship of Medicine and Post-Graduate Medical Association for next session will begin on Wednesday, October 11th, when the opening lecture will be given by Sir James Galloway on "The symptoms and treatment of certain unexplained granulomatous diseases." Dr. Eric Pritchard and Dr. C. E. Lakin will give lectures during October, and the complete programme up to December 13th will be published shortly. As already announced, a special course in tropical diseases will be given at the London School of Tropical Medicine from October 2nd; it will consist of twelve meetings, distributed over four weeks, on Mondays, Wednesdays, and Fridays, from 2 to 4 p.m. The syllabus will be available shortly. Owing to the nature of such a course, the class must consist of not fewer than four members, and it is therefore necessary that those desiring to join should notify their intention of doing so as soon as possible to the Secretary, Fellowship of Medicine, 1, Wimpole Street, W.1.

THE Harveian Oration will be delivered before the Royal College of Physicians of London by Dr. Arnold Chaplin, on Wednesday, October 18th, at 4 p.m., at the College, Pall Mall East. The Bradshaw Lecture will be delivered by Sir Maurice Craig, on "Mental symptoms in physical disease," on Thursday, November 2nd, at 5 p.m. The FitzPatrick Lectures will be delivered by Dr. R. O. Moon, on "Philosophy and the post-Hippocratic school of medicine," at 5 p.m. on Tuesday and Thursday, November 7th and 9th.

DR. GEORGE HASWELL WILSON, lecturer in bacteriology at the University of Glasgow, has been appointed to the Chair of Pathology in the University of Birmingham, rendered vacant by the election of Professor J. Shaw Dunn to the corresponding post in the University of Manchester.

THE John Elliott Memorial Pathological and Bacteriological Laboratory at the Chester Royal Infirmary will be opened to-day (Saturday, September 16th), at 4 p.m., by Sir Humphry Rolleston, K.C.B., M.D., President of the Royal College of Physicians of London. The laboratory has been fitted and equipped by public subscription in memory of the late Dr. John Elliott, Honorary Physician to the Infirmary from 1895 to 1921.

THE late Dr. W. H. R. Rivers, F.R.S., left estate of the gross value of £2,655. He bequeathed to St. John's College, Cambridge, of which he was a Fellow, the portrait of himself by Shields; to the college library such of his books as the authorities may choose; to the university the balance of his books; and to his friend, Professor G. Elliot Smith, M.D., F.R.S., all his manuscripts, with £500 for defraying the cost of their preparation and publication.

THE National Council for the Promotion of Race-renewal, which established the National Birthrate Commission, is organizing an International Congress for the Reaffirmation of the World's Moral Ideal to be held in London, October 15th to 22nd. The Congress will be opened at Caxton Hall, under the Presidency of the Bishop of Southwark, on Tuesday morning, October 15th. The afternoon session, presided over by Dr. Mary Scharlieb, will discuss marriage and parenthood and the relation of the sexes, the speakers including Dr. H. Crichton Miller, Mr. C. J. Bond, F.R.C.S., and Dr. J. W. Ballantyne. On Wednesday morning the subject for consideration will be the economic, social, and racial aspects of morality and the rise and fall of population, migration, etc., the speakers including Sir Arthur Newsholme, K.C.B., M.D., Dr. C. W. Saleeby, and Professor William Caldwell, D.Sc., of McGill University. All communications about the Congress should be addressed to the General Secretary, Sir James Marchant, K.B.E., LL.D., 60, Gower Street, London, W.C.1.

He said that the term "efficiency" had become a mere catchword, and practically it had come to mean, to the average man in the street, the mythical improvement which

was to be anticipated from some change in workshop or office organization—a bigger and hotter result at a smaller cost. The word had a very definite meaning in engineering science, and this meaning had been transferred from the inanimate machine to the living organism. In the case of the engine the problem was relatively simple, as the number of interfering factors was not great; but the solution of the problem in the case of the organism was beset with many difficulties, as the interfering factors were numerous and varied.

Factors Influencing Efficiency.

The design of the organism which had to stand the strain was not at fault. It was an organism which, in the language of the engineer, was abundantly supplied with factors of safety, and had an over-all high factor of safety. The body was not designed merely to perform the minimum amount of work or to stand the minimum strain; there was always a reserve. We had a circulatory system which was beautifully balanced to meet a strain, a system of vessels whose calibre could be increased or diminished so that the blood might be mobilized at the tissues of the organs which required it, and a heart which had the capacity, provided it was normal and healthy, of responding to work, whose rate might be trebled in a few seconds when oxygen had to be obtained and carbon dioxide got rid of. Not only could the amount of blood which was passed through the lungs during hard work be increased some five times, but the amount of oxygen taken in might rise ten times. At rest less than a third of the oxygen present in the blood was required, and even in the very hardest work the arterial blood was not depleted of its oxygen; it probably still contained more than a fourth. The actual effectors, the muscles, did not of themselves seem to have a very high factor of safety. The structures—bone and cartilage—to which they were attached, and which limited their action, and the amount of strain to which they could be exposed or subjected, had a very high factor of safety.

The efficiency of a man did not merely depend on the amount of work which could be performed by his muscles; the circulatory, respiratory, and nervous systems were of equal importance, and all were intimately related. The muscles had to receive an abundant supply of blood, not merely to bring nutriment, but to remove waste; there had to be an efficient exchange of gases in the lungs, the rate of the respiratory and cardiac movements had to be adapted to the work in hand through the co-ordinating agency of the central nervous system. Not only so, but if the man was to work with the minimum of waste energy there had to be proper co-ordination between the various groups of muscles. Turning to the consideration of the factors which influenced the efficiency, both in the mechanical and industrial sense, it was found that the main controlling factor was undoubtedly the condition known as fatigue. "Fatigue" was a word just as frequently used as "efficiency," and yet it was almost impossible to give an accurate definition of the term. Generally speaking it was to be regarded as the antithesis of efficiency.

Rate, Rhythm, and Rest.

The factors which played predominant parts in the attainment of maximum efficiency were the rate of the performance of work, the amount of rest taken or offered by the subject, the rhythm with which the work was performed, and the work habits developed by the worker. These were all intimately related, and usually merged into one another. Of these four factors probably most attention had been devoted to the rate of speed at which work was carried out, and the glorification of that much misused half-truth, "Time is money," was responsible for much false physiology. Benedict and he had found, working with a carefully calibrated bicycle ergometer, that there was a very close connexion between the speed at which work was done and mechanical efficiency. There was a very definite falling off with increased speed. They found, further, that if the amount of effective muscular work was kept constant the efficiency fell with an increase of speed.

The load had obviously a direct connexion with the speed at which the work was done, but it had also a relation to efficiency. Benedict and he found, for instance, that both the gross and net efficiencies, within the limits of their experiments, increased with the load. The probable explanation of that result was that, when light work was carried out, maintenance of physiological requirements which had to be covered formed a large proportion of the total energy output, a balance which was steadily altered as the amount of external effective work done increased. On the other hand, when the loads became excessive there was a definite falling off both in gross and net efficiencies.

Very closely allied with the rate of working was the rhythm with which the work was performed. Although they were not identical phenomena, they were so closely related that the habit of work might be considered along with rhythm.

Once a rhythm, or the proper co-ordination in the play of a set of muscles in the performance of some definite act, was mastered, not only was the energy expenditure reduced by the exclusion of numerous extraneous muscular activities, but the ease of performing the specified act was enhanced. Willingly or unwillingly those who had to do much repetitive work—whether it were playing golf, a musical instrument, or working a machine—soon appreciated the fact, when they thought about it at all, that their best and easiest results were obtained under certain very definite conditions. To take a single example, the work of forward progression, or walking, was performed most easily when a person adopted his own gait; it was not a mere question of rate.

The rhythm of work was simply a general example of the formation of a conditioned reflex. The rhythm adopted, although it might suit the worker, was not of necessity a series of muscle movements which led to the least expenditure of energy. Most probably the rhythm selected was only in small part due to the worker's physical configuration; in greater part it was evolved in imitation of some more experienced or older worker. The average workman was not so much concerned with the diminution of the physiological cost in the performance of a given act as in the reduction of constant effort.

On measuring efficiency in terms of output, a definite rhythm of output was found during the course of the working day and of the working week. The fact that it took an appreciable time each day to work up the full power was shown distinctly in the daily output curve, which rose and then dropped sharply at the end of the work period; this type of curve was not peculiar to any one industry. The rise was almost certainly due to the "lumbering up," and it was probable that the fall towards the end was largely due to voluntary slowing. The total weekly output curve, with the low Monday effect and the sharp fall on Saturday, resembled in general shape the daily output curve. Such curves seemed to demonstrate the absence of progressive fatigue from overwork, which would have been deduced had there been a sharp rise at the commencement of the week followed by a steady fall.

The third of the potent factors in the control of fatigue was rest. If work was done, rest was ultimately imperative. Rest not merely relaxed the muscle, allowing a more thorough and complete removal of the waste products and a more abundant supply of oxygen, but it removed the strain of attention. Rest was best obtained not by simple quiescence, but by change of posture or slow movement of another type. Little attention had been paid to the duration of the rest period in relation to the work done. As a general rule it might be said that in the majority of occupations, although the hours of labour were continuous, the actual spells of hard manual work were discontinuous, either due to the fact that certain operations were intermittent in their severity, that supplies of material were not constant, or that if those more or less natural conditions did not operate rests at irregular intervals were deliberately taken by the operative.

Relation of Food to Efficiency.

There were many other factors directly concerned with the efficient action of the organism, some directly influencing the internal economy of the body, others acting more indirectly on the organism from the environment. One was the state of the nutrition. An insufficient intake of food, or the consumption of poor or inadequate food, was one of the chief sources of general inefficiency. Our resistance to the effects of hard and continual work, just as to the effects of an infection, was largely controlled by our reserves. The capacity of the body to store reserve food material which would meet the daily demands for energy, and leave a surplus, was another of the vital factors of safety, capable of withstanding complete deprivation of food for comparatively long periods, but with a corresponding depression in its capacity to perform external work. Complete starvation was a state which was rare and did not affect the question. Chronic undernutrition was only too common—a condition which lowered efficiency, not merely in the actual performance of muscular work, but by inducing an increased susceptibility to disease. Evidence, much debated it was true, indicated that it was not only the quantity but the quality of the food consumed which played a part in the fitness of the individual to perform hard muscular work. All modern work seemed to point to the conclusion that if the calorie value of the food supplied was adequate the actual demand for protein was very small. It was very difficult, however, to believe that the far-reaching common belief in the efficacy of a high meat intake, despite the scientific evidence to the contrary, was without some foundation.

The Psychological Factor.

Another factor which played an enormous part in the general efficiency was the response of the organism to the multiple psychic imponderabilia which composed such a

large part of the average environment. We had to deal with an organism which was not only under physical control, but which was very responsive to psychic influences—an organism which not only became in the course of the day physically "tired" but which unconsciously was influenced to an enormous extent by its environment, by its "atmosphere." In this connexion monotony of work had to be considered, yet, although there might be a close relationship between monotony and fatigue, they were not identical. The temperament of the operative played an enormous part in the determining of whether or not any particular operation was a monotonous one.

Many other factors played a definite and important part in the maintenance of efficiency, such as lighting, heating, ventilation, the mode of life led by the worker outside his definite hours of labour, his housing, etc. In other words, the real "over-all" industrial efficiency of the worker could not be causally related to any single factor. The quest of efficiency was one of the most intricate problems, in its infinite ramifications throughout the physiological and sociological structure, which had ever called for solution. It called for the closest co-operation between the scientific investigator, the employer, and the employee, and was no more capable of being settled on a communistic than on a capitalistic basis. It could only be satisfactorily attacked when mutual distrust of motives, capacities, and methods was stilled.

NOVA ET VETERA.

STYLE.

In speaking of Sydenham a short time ago (August 19th, p. 320) we ventured to say that his Latin was very unattractive, and we are tempted to return to the subject by the hope that we may stimulate better scholars to discuss the ingredients of a good modern Latin style. Generally speaking, Macaulay's advice, "Soak your mind with Cicero," has been given by the professional scholars. Marc Antoine Muret has been called the prince of modern latinists; Wyttewbach said, "If I have attained any little skill in writing, I owe most of it to reading Muret's works; his wonderful smoothness charmed me as a boy, helped me with examples, and led me back to Cicero."¹

Sydenham, or his translator, went back to Cicero, but, as Dr. Payne showed, hardly found there what he wanted. For instance, in what was perhaps his first draft, Sydenham, having said that diseases differ from year to year, has this plain sentence: "Both which doo ovineo that they are of quite different genius and nature."² The Latin version runs: "Ex quibus constat morbos hosce utit quadantenus specie et symptomatis alieno admodum osso indolis et distoro ut aera lupinis." The last phrase, as Dr. Payne said, is just the sort of tag with which a phrasemaker might swell out a plain sentence. Perhaps one may quote Erasmus: "Si provisorot ipse Cicero, ridoret hoc Ciceronianorum genus." We should very much like to know whether a good scholar would rate Sydenham high or low as a stylist.

Some medical latinists who had a great reputation have used a much simpler style. Of such was Josso van Lomm, often called the "elegant Lommus," whose style was praised by Haeser. Lomm is much easier to read than Sydenham; here is a fair specimen of his manner: "Noque enim parvi roferre arbitror, quao ejusque morbi vis, aut acumen, aut duratio, aut eventus sit, observare; aequo profecto, ut in aliquem aliquis verti morbus possit, quibus aetatibus magis accidere, quibus temporibus anni, quibus coeli tempestatibus, quibus locis."³ Easy, straightforward, not too stately, but with a touch of verbal pomp; certainly not Ciceronian in the sense that Sydenham's published writings are Ciceronian.

Perhaps it was Lomm's style which kept him abreast of Sydenham as a popular author for so many years. Lomm had been physician to Philip II of Spain, and was dead before Sydenham was born, but between 1700 and 1750 Lomm's *Medical Observations* were reprinted eight times; the great Englishman's works only had four more editions than his in the same time. Probably our ancestors, for all their stateliness, liked things made clear, and Lomm made them very clear.

Very likely some people who, at the cost of many tears and some blood (*teste* Gibbon), were just able to read plain Latin wanted to know what *synochus* meant; how a continued

fever differed from a putrid continued fever; what a "slow fever" really was; and how to unravel the tangled skein of quotidian, tertians, semiteritians, quartans, and so on.

Such readers must have been delighted with the elegant Lommus; having read him once they would know all about it. They would know that a *febris continens* was merely due to heated blood, that a *febris continens putrida* was due to putrefaction of blood and nothing else, while a *febris continua putrida* was bred of a systematic humoral corruption and different from a *febris lenta*, a more localized humoral putrefaction. Better still, the terrible complexities of the intermittents—a colloquy "viva" on Galen de *Februm Differentiis* must have been an awful ordeal—are reduced to their lowest arithmetical terms.

Lomm deserved and received the gratitude due to anyone who writes quite plainly, says what he has to say, without quoting needless Latin if he writes English, and without dropping into poetry if he is writing Latin. His style, of course, could not save him for all time, because, like another forgotten writer (Lord Jeffrey, described by Matthew Arnold), he "had no gift for truth." The prognostic significance of the Hippocratic facies is described neither more clearly nor less clearly than the prognostic significance of dreams. No doubt is hinted as to whether dreaming of a fire is a really sound indication that the yellow bile is amiss or as to whether a topographical diagnosis can be founded on a dream of sun, moon, or stars. Sooner or later someone was bound to discover that the prognostics from dreams were not derived from the elegant Lomm's observations upon King Philip, but lifted from the fourth book de *Vitu* in the Hippocratic collection (Galen has most of them in his little tract, but he shied at the sun, moon, and stars). That discovery made, a reader would begin to doubt even about the synochus and the intermittents, and that would be the end of the elegant Lomm and his kind. Sydenham certainly said some very queer things about the use of nasty-smelling drugs in hysteria and had a weakness for puppies as hot-water bottles, but he had nothing to do with dreams. Perhaps we ought not to laugh either at Lomm or at the fourth book de *Vitu*, because some learned American may yet prove them to be allegorical foreshadowings of a doctrine which we do not mean to discuss.

We suppose Lomm will never be reprinted again, but a selection of the writings of physicians eminent for their latinity would really be worth making. It would begin, we suppose, with the greatest of all the stylists who, using his mother tongue, said this: "A suturis se deceptum esse, Hippocrates memoriae prodidit; more scilicet magnorum virorum, et fiduciam magnarum rerum habentium. Nam loria ingenua, quia nihil habent, nihil sibi detrahaunt; magno ingenio, multaque nihilominus habituro, convenit etiam simplex veri erroris confessio; praecipueque in eo ministerio, quod utilitatis causa posteris traditur; ut qui decipiantur eadem ratione, qua quis ante deceptus est."

To soak one's mind with Celsus might be better advice than to imitate Cicero.

MINISTRY OF HEALTH: ANNUAL REPORT.

SECOND NOTICE.

In the JOURNAL of July 29th (p. 184) we gave a brief account of the parts of this report relating to tuberculosis, venereal diseases, maternity and child welfare, welfare of the blind, and the work of the Welsh Board of Health. Two further matters of medical interest and importance remain to be noticed—Housing and National Health Insurance.

Housing is dealt with at some length in the report. The problem, it is stated, entered on a new phase in the year 1921-22. Difficulties due to shortage of capital, labour, and materials, and to the inauguration of a comprehensive policy, had tended to diminish, but on the other hand the cost of building had become so high as to render imperative the limitation of the amount to be undertaken at the expense of the Exchequer, and it was hoped that such limitation would help towards deflation of prices, so as to pave the way for the resumption of private enterprise. It is claimed that the policy has been successful, as proved by reductions of tenders from £944 and £855 to £450 and £378, with anticipation of further decreases. But the urgency of improvements in slum areas was such that an annual contribution not exceeding £200,000 was determined on in aid of this part of the work of local authorities. The houses completed under various schemes at March 21st,

¹ See preface to M. Antonii Maroti, *Scripta Selecta*. Leipzig (Teubner), 1887.

² *The Life of Sydenham*. By J. F. Payne, London, 1902, p. 219.

³ *Idoloci Lommii, Observ. Med.*, 4th ed., Amsterdam, 1738, p. 281.

1922, were 130,335, and of these completions fully 100,000 belonged to the year under review. There still remained 75,484 to be erected under the final scheme by local authorities and public utility societies, and of these 52,417 had already been commenced. Besides this, preliminary certificates had been issued in respect of 12,295 to be erected by private builders. Recent reductions of price, however, did not greatly diminish obligations already undertaken, and the subsidies paid during the year amounted to £4,533,229. As to rents, agreement had been reached with about 1,103 local authorities, and the range, exclusive of rates, was from 4s. 6d. weekly for a four-roomed house in a rural area to £1 ls. weekly for a six-roomed house in a popular residential locality in the metropolitan area. The loans raised by local authorities under the State-aided schemes amounted to £152,000,000 at the end of March, 1922.

Under the Public Health Acts and the Housing Act of 1890 reports by medical officers of health in 1,503 districts show over a million inspections and remedy of defects in 180,699 houses. Under the Act of 1919 notices were served in respect of over 30,000 houses, of which nearly 20,000 were rendered fit by their owners, 801 by local authorities, and 425 were to be closed. Under the Public Health Acts notices were served for more than a quarter of a million houses, and defects were remedied in over 220,000, including nearly 2,000 done by local authorities instead of by the owners. Town-planning schemes were occupying the attention of 167 local authorities at the end of the year, and the total area embraced was 744,222 acres.

National Health Insurance.

Up to October, 1921, Insurance Committees had forty to eighty members; now they have twenty to forty. Questions relating to the scope of medical benefit ("such treatment as" can "be properly undertaken by a general practitioner of ordinary professional competence and skill") were in thirty-one cases reported to the department. Of twenty-two, where the local Medical and Insurance Committees were agreed, seventeen were decided to be outside the definition and five within it. Of the other nine cases, six came before referees; four of them were declared to be within and two not within the definition. In three cases sent to referees by the Ministry itself, one was found within the definition and two were not. Medical benefit in England cost about £8,250,000, of which about £5,885,000 was paid to the doctors and the remainder nearly wholly spent on drugs and appliances. The insured population is about 12,500,000. Besides the above expenditure about £250,000 was distributed to rural practitioners for mileage. Drugs and appliances cost about £1,250,000. The payment made to chemists, apart from the price of ingredients, was about 5½d. a prescription, but was reduced to 4½d. as from May 1st, 1922. It is pointed out that "no insurance practitioner can be penalized in any way as a result of his prescribing particular drugs or appliances" unless it is found, after inquiry by the Panel Committee, consisting entirely of the doctor's fellow practitioners, that "the cost is in excess of what may reasonably be necessary for the adequate treatment" of the patient. Also it is pointed out that "this duty has been entrusted to the practitioners themselves at the request of their own representatives, who have undertaken that the work should be fairly performed."

During the year, on account of unsatisfactory standard of service, Exchequer grant to the total amount of £1,118 was withheld from seventy doctors and six chemists. In four cases of doctors £50 was withheld, and in two cases £40. "In four of these cases the doctor was found to have been guilty of serious neglect of patients. In one case the doctor permitted his wife to attend patients, though she held no medical qualifications, and in another the doctor persistently charged the patient fees for services which he was under contract to render free of charge." From one chemist £50 was withheld in respect that he "repeatedly supplied smaller quantities of drugs and appliances than those ordered by the doctor."

Fourteen inquiries were held as to removal of practitioners or pharmacists from the medical list on the ground that their continuance would be prejudicial to the medical service. Eleven related to doctors, three to pharmacists. Three of the doctors had been convicted of criminal offences; two of these were removed from the list, and in the other a decision was deferred for twelve months, regard being had to the doctor's conduct in the meantime. In two cases the complaint was neglect of patients. One of the practitioners died

and the other was allowed to resign on condition that he would not resume insurance practice without the Minister's consent. In three cases the representations were withdrawn, and one case was dealt with by the General Medical Council. In the three remaining cases the grounds alleged were insufficient to justify an inquiry. Two pharmacists were removed from the list and the third had £50 deducted, besides having to pay the costs of the inquiry.

Against decisions of Insurance Committees there were sixteen appeals, eleven by doctors and five by insured persons or societies. Of the eleven, six were dismissed, four allowed, and one withdrawn. Of the other appeals, one decision was varied, one was dismissed, and in two no sufficient grounds of appeal were shown. In ten cases the doctor appealed against a decision of the Insurance Committee to withhold part of his remuneration on the ground of excessive or extravagant prescribing. Two of the appeals were dismissed (the Insurance Committee in one case agreeing to reduce the penalty), one appeal was allowed, one withdrawn, and in the rest the amount of surcharge was reduced.

New certification rules took effect from January 1st and certain amendments were made in the scheme. The new forms of record have been found generally acceptable to practitioners. The Committee on National Expenditure recommended that to relieve the Exchequer of payments beyond its statutory two-ninths there should be an increase in weekly contributions, but the approved societies preferred to pay the requisite amounts out of their surpluses and balances. This was agreed to up to the end of 1923. The Women's Equalization Fund was abolished and the necessary financial assistance to societies will be provided by increasing the reserve values in respect of married women, the period

fixed by between one and two years. The valuation reports, made available by the valuation reports, came into operation on July 4th, 1921. The benefits selected by the societies are of two sorts—cash, or forms of remedial treatment. Societies with a membership of 3,896,258 decided on cash benefit only; others, with a membership of 4,392,461, decided in favour of a combination of cash and other benefits; and societies with a membership of 4,112,298 decided to devote their whole available surplus to other than cash benefits. In the first of the three groups the cash increase ranges normally from 1s. to 5s. a week of sickness benefit; 6d. to 2s. 6d. a week of disablement benefit; and 2s. to 10s. of maternity benefit. Thus the total weekly sickness benefit may vary from 16s. to 20s. for men and from 13s. to 17s. for women; disablement benefit from 8s. to 10s. weekly; and maternity benefit from 42s. to 50s.

THE FATAL CASES OF FOOD POISONING AT LOCH MARÉE.

[FROM A CORRESPONDENT.]

THE outbreak of food poisoning at Loch Marée has been referred to recently in the BRITISH MEDICAL JOURNAL on several occasions, and the last may not have been heard of outbreaks of botulism in this country. The sheriff's inquiry was held on September 5th, 6th, and 7th at Dingwall, under the Fatal Accidents Inquiry Act; in this he had the assistance of a jury of seven, four of whom were women. The jury attributed the cause of death of eight persons (which included all those who were attacked) to poisoning by eating sandwiches that contained canned wild-duck paste infected by *Bacillus botulinus*, an anaerobic organism. The jury found that there had been no negligence on the part of anyone concerned, including both the manufacturers of the paste, who were a London firm of high standing, and the hotel proprietor, and that it was not possible to specify what precautions should be taken in future in order to avoid the occurrence of a similar accident. A rider was added to the effect that every vessel containing preserved meat, fish, fruit, or vegetables intended for human consumption should bear a distinctive mark by which, if necessary, details of manufacture might be traced.

Thus the inquiry ended very much in the way which might have been anticipated, no blame being attributed to anyone. But the epidemiologist in the result emerges, unfortunately, little wiser. The main point of interest, epidemiologically, arising from the investigation is that Great Britain is no longer immune from outbreaks of botulism. It may be suggested, judging from foreign experiences, where the articles of food incriminated ranged from sausage and ham

on the one hand to canned beans and olives on the other, that the next outbreak in this country is not more likely to be associated with potted food paste than with many other food-stuffs. This attitude, unfortunately, is necessitated by our lack of knowledge as to how these outbreaks arise. It is known from laboratory tests that much more than a lethal dose of *B. botulinus* or its toxins may be administered to an experimental animal, and if a suitable dose of botulinus antitoxin be administered simultaneously or therabouts illness is not produced. We do not know, however, whether this antitoxin would be of value in saving life if it were administered to a human case as soon as a diagnosis of botulism were made.

A very striking feature in the diagnosis of botulism is recognition of the phenomenon of double vision some hours before any other subjective symptoms are noticeable. The patient at this stage apparently may be in normal health, apart from the presence of diplopia. An American citizen visiting this country was present some three years ago at a banquet in the State of Ohio which was followed by an outbreak of fatal botulism due to bottled olives from California. He states that in one instance diplopia suddenly manifested itself when the victim was driving a motor car; another could not understand why two persons walking in the street were, as he thought, performing simultaneously identical antics; and another was puzzled by his inability to remove from a plate one of the two peaches seen by him. Up to this point these persons appeared otherwise to be in good health. Similar instances of diplopia were reported from Lech Marce; one of the victims, for instance, was struck by the fact that a companion was smoking two pipes, and indeed there appears to be no difference whatever between the clinical accounts of botulism in the United States and the Lech Marce experience.

Treatment is most unsatisfactory. The main hope would appear to lie in the use of the specific antitoxin. It is available as a result of work done in the Wellcome Research Laboratories in connexion with the prevention and cure of "grass sickness" or "grass disease" in horses, which is ascribed to botulism. It was announced at the inquiry that arrangements were being made for a supply of this antitoxin to be obtained, in case of necessity, by application to the Ministry of Health, and that the serum would be placed at a number of suitable provincial points; Plymouth, Cardiff, Birmingham, Manchester, and Newcastle-upon-Tyne were mentioned, and the Scottish Board of Health was to take similar steps for Scotland. Other centres, such as Norwich and Chester, might perhaps be included also. In view of the urgent need for commencing intravenous injection of this serum, amounting eventually to about 50 c.c.m., as soon as the diagnosis is established, in order to overtake if possible the effects of the toxin, the prospects of a sufferer at, say, Carlisle or Newcastle would be much prejudiced if recourse had to be made to London, as he would be fortunate in the circumstance if he received his first injection within twelve hours of the need for its administration being realized. In view of the Lech Marce outbreak the subject of "grass sickness" or "grass disease" in horses deserves close attention. This "grass disease" has been known in the north (and more recently in the south) of England and in Scotland now for some years; a specially appointed Science Committee of the Highland and Agricultural Society of Scotland was appointed to investigate it in 1918. The symptoms are identical with "forage poisoning" in horses and cattle in the United States of America, and the disease has been found to be due to an organism reported to be indistinguishable from *B. botulinus*. This organism was recovered early in 1919 by Dr. Tocher of Aberdeen from the intestines and spleen in several cases of "grass sickness" in horses. At the Lech Marce inquiry little was said as to the possibility that this outbreak of poisoning in man was associated with this particular disease in horses. If, however, there is an association between attacks of botulism in man and "grass sickness" in horses—and, as is known, this disease in horses is widely disseminated in Great Britain—it would be hazardous to prophesy what is likely to happen in the future.

Some positive evidence is available which is reassuring. *B. botulinus* can live only under anaerobic conditions, and its toxins are killed at a temperature much below that reached by the ordinary method of canning. The spores are, however, more resistant, for they are not killed until temperature considerably above boiling point is reached.

"Grass Disease and Botulism." By J. B. Buxton, F.R.C.V.S., D.V.H. *Veterinary Journal*, April, 1922.

and maintained; but this temperature is attained during the process of sterilization under pressure in retorts as usually practised in food-canning factories. Why one individual vessel containing food paste contained this deadly bacillus is as yet unexplained. Obviously, the bulk of the paste as prepared and mixed on a large scale in the factory could not have been infected, as all this stock has in the ordinary process of trade been put into circulation; most of it must have been consumed, and no adverse results have been reported. No doubt the consumption of canned goods in this country will fall off for a time; but it is comforting to remember that in spite of the many million containers of preserved foodstuffs, including food pastes, supplied to the armies during the recent war, whether issued to troops as rations or sold in enormous quantities in canteens, no outbreak of botulism was reported in connexion with their consumption, either at home or abroad.

Scotland.

REPORT OF THE MEDICAL OFFICER OF HEALTH FOR GLASGOW FOR 1921.

THE annual health report of the Second City of the Empire is a leafy volume of 175 pages and deals with many matters of public interest. Population, housing, and occupations have already been referred to in the *JOURNAL* in articles on the census (August 26th, p. 399) and on the Registrar-General's Annual Report for 1920 (July 29th, p. 178). In 1921 a new minimum death rate of 14.5 on the estimated population of Glasgow has been achieved, and also a new minimum infant mortality rate of 105 per 1,000 births. These figures have to be judged in relation, not to certain lower rates elsewhere, but to the housing and other conditions of life in Glasgow itself.

As regards housing, Dr. Chalmers calls attention to its moral aspects, a subject which, under the title of *Life in One Room*, called forth one of the most eloquent and pathetic contributions ever made to the literature of public health, the author being the late Dr. J. B. Russell, the predecessor of Dr. Chalmers in his important office. Under the heading "Sex overcrowding in small houses," Dr. Chalmers gives some appalling examples.

"In a one-apartment house, a father of 52 occupied the same bed with a mentally defective daughter of 24, who had an illegitimate child of 10. In another, with space for five adults, a father and daughter shared the same bed. In another, with space for two and a half, the same bed with two sons of 19 and 20 years. Illustrations of this were disclosed, as well as fathers and daughters. In several illustrations the mothers occupied the same beds with grown-up sons and daughters."

In two-roomed houses, in one instance a son of 19 and a daughter of 21 occupied the same bed, and in another a son of 19 and a daughter of 25, who was pregnant. These are revolting facts, but it is right that the public should be made aware of them. As regards available housing accommodation, which a reader naturally thinks of in connexion with such revelations, there appears to be a curious discrepancy between the data furnished by the City Assessor of Glasgow and the Census Report. According to the former, whilst there were in 1911 24,206 empty houses, there were only 143 in 1921. But, as pointed out in a footnote by Dr. Chalmers, the new Census Report gives the "unoccupied" houses in Glasgow as 11,539. The difference is much too great to be accidental. The assessor's word "empty" cannot mean the same thing as the Registrar-General's word "unoccupied," and the reader may speculate that the unoccupied houses were those temporarily closed owing to households being on holiday in June when the census was taken, this agreeing with Dr. Chalmers's contention that the population was unavoidably understated. The report, however, contains a table in which the two words "empty" and "unoccupied" seem to be regarded as interchangeable, and which shows that the unoccupied or empty houses, now only 143, had been in 1913 no less than 18,710.

Maternity and Child Welfare.

With the co-operation of an advisory committee, classes on cookery and dressmaking have been begun, and social evenings arranged for.

Infant consultations are conducted at thirteen centres, and the total attendances in 1921 were 61,621, as against 44,237 in 1920. Of infants under 1 year the attendances were primary 7,811; and subsequent 40,434; of children over 1 year, 3,187 primary, and 10,185

subsequent. At the ante-natal dispensary at the Royal Maternity Hospital there were 6,034 attendances, against 3,151 in 1920. In the ante-natal wards the average number under treatment was 28, the number of admissions 703, and the total days 10,318—all considerable increases over previous years. At another institution, the Govan Nurses' Home, there were 771 attendances. Infant visitation is carried on extensively where birth notifications do not show that a doctor was in attendance. Full information was obtained regarding 22,216 births; 18,768 infants were reported well nourished at birth, 1,518 fairly nourished, 801 badly nourished, and 816 still-born. The Infant Health Visitors' Association keeps under observation children reported to it as requiring longer observation than can be given officially. There are from 300 to 400 visitors, and the period covered is generally the first year of life. In 1919 the number of infants so dealt with was 2,179. The Corporation administers seven day nurseries, and the total attendances during 1921 were over 32,000. Two country homes received 182 children.

Supply of Milk and Meals.

Much detailed statistical and financial information is given on this subject, in which the Corporation co-operated with the education authority, these being separate public bodies in Scotland. The times were exceptional in respect both of high prices and of poverty. It has to be borne in mind that in Scotland the Poor Law authorities can, in theory, give relief only to persons who are not only in poverty but also unfit to work. In practice, however, that rule had to be relaxed, but, even so, a heavy burden fell on the public health and education authorities. The risks of overlapping and also of lacunae in any such tripartite system of rate and State aided relief are obvious, and bring to mind the recommendation of the Minority Report of the Royal Commission on the Poor Law, supported as it was by their medical investigator for England and Wales, that public health and Poor Law should be administered by one and the same local body. In such work the definition of "necessitous" as a basis for relief must always be difficult, stringency and laxity each having dangers of its own, the effects of the latter being illustrated in the present revolt against "Poplarism" in London. Glasgow Corporation has its "right" and "left" parties, and no doubt the usual clash of opinions took place, but such matters are not within the scope of the medical officer's report. In December, 1920, the local authority and the Scottish Board of Health approved of a scheme which came into operation in January, 1921.

The growth in the demand for milk for expectant and nursing mothers is indicated by the fact that between February 5th and December 23rd, 1921, the number of mothers obtaining milk under the Glasgow scheme, apart from the Poor Law, increased from 192 to 5,151, of children under 5 years from 58 to 13,234, of pints of milk from 826 to 18,385 a day, whilst the daily cost grew from £18 to £275. As to meals, distress reached its climax on the occurrence of the coal strike in April, and at the beginning of May a scheme of dinners was begun for mothers and children, which by the end of the year had provided 952,608 meals, of which 409,001 were for mothers, 309,971 for children of 3 to 5 years, and 233,635 for infants from 9 months to 3 years.

Details are given of the economic conditions relating to family, employment, and income, which were considered in the granting of assistance; in an appendix there are tables of income and occupation which may furnish material for students of sociology.

Ophthalmia Neonatorum.

In 1921, 926 cases were notified as against 787 in the previous year, but this is explained partly by increase of births and partly by the influence of a circular issued by the Scottish Board of Health in July regarding precautions to be observed, especially the application to the eyes of newborn children of a 1 per cent. solution of silver nitrate. This has resulted in more care being taken, and more slight inflammations being notified.

By doctors 97 cases were notified, by institutions 60, by institution nurses 198, and by midwives, etc., 566. The periods at which symptoms appeared were: under twelve hours, 102; twelve hours to four days, 423; four to eight days, 257; and over eight days, 134. The results of treatment are tabulated in detail; 745 were entirely cured, and no case of total blindness occurred. Mothers were offered treatment for the venereal disease which caused the ophthalmia in their offspring, but few continued under it until cured. Of 30,072 births during the year, 15,212 were attended by midwives, and of these 12,000 occurred in the practice of midwives with fifty confinements or more in the year. The number of midwives in practice was 364. They notified 418 cases of ophthalmia neonatorum and 112 of puerperal fever. In Glasgow in 1921 there were 10.8 cases of puerperal fever per 1,000 births, as against 9 in 1920 and 7 in 1919. The increase, Dr. Chalmers remarks, may be partly due to notification of short-lived rise of temperature.

Principal Zymotic Diseases.

If the term be applied throughout in the same sense these diseases have had a lower total mortality in 1921 than in any

previous year, the rate being only 1.116 per 1,000 living, as against 3.600 in the decade 1881-90, 3.282 in the next decade, 2.660 in 1901-5, 2.450 in 1906-10. In the past six years the rate has exceeded 2 per 1,000 only in 1917.

Small-pox, of which there were 477 notifications in 1920, had only 19 (or 20?) in 1921. Diphtheria has a curious case mortality rate in respect that in 1920 and 1921 the fatality rates of cases treated at home (15.5 and 13.8 per cent.) were just about the double of the hospital case rates (7.6 and 6.6); whilst in 1919 the position was just the opposite, the home fatality rate being 4.4 per cent. against 9.1 in hospital. But only 5 to 10 per cent. of all cases were treated at home, and as the annual totals averaged about 1,800 the 5 to 10 per cent. afforded no great basis for fatality rate conclusions.

Concerning erysipelas and perhaps also puerperal fever, Dr. Chalmers seems to suspect that relaxation of restrictions on sale of liquor has tended to increase the numbers, as compared with war years. Malaria and dysentery were treated at three dispensaries, and the total attendances were 7,154. Dr. Chalmers reprints from the *Glasgow Medical Journal* a report by Drs. Macgregor and Frew on the treatment of amoebic dysentery by alcrestia and emetinc. Diarrhoea and enteritis caused an excessive number of deaths among children, no doubt owing to drought and heat, so it is all the more satisfactory that, as already noted, the year's infant mortality rate was the lowest on record. Phthisis had a death rate of 1.007 per 1,000, also its lowest on record. In 1881-90 the rate was 2.680; in the next decade 2.015, in the next 1.533. In each of the last three years the rate has been under 1.1. In the years 1914-20 inclusive, Edinburgh, Aberdeen, Dundee, and Birmingham had lower rates, whilst Liverpool and Manchester had higher. The Glasgow notifications also were low in 1921.

Omissions to notify before death occurred in 3.6 per cent. of the cases. The number of cases treated in institutions has just about doubled since 1914, the total that year having been 1,690 and in 1921 3,287. At dispensaries primary attendances were 2,542, and subsequent attendances 57,825. Home visits by nurses numbered 40,161, being a large diminution on the two previous years. A fund of about £400 a year has been established to provide warm clothing for poor patients going to sanatoriums, and has met a real want. Intimations of non-pulmonary tuberculosis show some diminution since notification became compulsory on July 1st, 1914. Admissions of such cases to institutions have increased from 17 in 1915 to 1,019 in 1921.

Venereal Diseases.

Much detail is given of accommodation and provision for treatment of these diseases. Dr. Chalmers believes that opinion is gradually crystallizing round the need for some modified form of notification—perhaps, to begin with, the notification of cases where third parties suffer, as in congenital syphilis and ophthalmia neonatorum. As to medical education on the subject of venereal disease, Dr. Chalmers thinks it should be improved, the successful treatment of gonorrhoea demanding skill and knowledge of instrumentation obtainable only by devoting to it considerable time. Syphilis treatment is more easily learned. It is unfortunate, he says, that more practitioners do not avail themselves of the facilities for post-graduate teaching of the subject in Glasgow, and that only 12 out of about 500 practitioners in Glasgow have during the year taken advantage of the free supplies of salvarsan available.

Port Sanitary Administration.

Glasgow is the port authority, not only for its own area, but for parts of the Clyde lower down. A detailed report is given of work done under the regulations of the Scottish Board of Health, and as to disembarking quays, boarding by Customs officers, work under the Aliens Order, and boarding and removal of the sick.

Vessels arriving from foreign ports numbered 1,242, of which 421 had come from ports infected within the meaning of the Cholera Order. The total crews in the course of the year were 66,968, and passengers 12,891. During the voyages 128 cases of infectious disease occurred, of which 47 were dealt with at other ports and 81 on arrival, 46 being removed to hospital and 35 sent home. Six died during the voyage. Alien passengers numbered 3,490, of whom 505 were transigrant. For discovery of nuisances 2,103 inspections of vessels were made, and 1,195 nuisances found. Of foodstuffs from abroad 715,075 tons were imported, and 1,635 tons were found unfit and disposed of to the satisfaction of the medical officer of health. The total packages of foreign meat imported were much fewer than in 1919 and 1920. A leaflet under the Rats and Mice (Destruction) Act, 1919, was given to all masters on arrival at the port. About 2,700 rats were destroyed.

Bacteriology.

Dr. R. M. Buchanan reports on the work done in the Public Health Laboratory regarding diphtheria, enteric fever, tuberculosis, Vincent's angina, malaria, dysentery, ophthalmia neonatorum, milk supply, and rats examined for plague. In

ROYAL EARLSWOOD INSTITUTION.
The report of the Royal Earlswood Institution for Mental Defectives (Redhill, Surrey) states that the number of patients at the end of the year was 439; 47 cases were admitted during the year, 10 of whom were classed as idiot, 35 imbecile, and 2 feeble-minded; 7 were mongolian, 5 epileptic, and 1 each cretin, hydrocephalic, and paralysed. In regard to the causes assigned for the mental deficiency in these cases, 12 were due to heredity, 7 had a history of phthisis, 7 had a history of injury during birth, 6 of shock or indisposition of the mother, 4 had congenital or acquired

deafness, 2 had convulsions during infancy, 2 had acquired or congenital syphilis, 1 was the offspring of first cousins, and 16 had no cause assigned. Little stress can evidently be laid on the supposed cause of the condition. The medical superintendent states that one patient who suffered from *petit mal* previous to admission, and was taking thyroid extract, had no attacks after admission when the thyroid treatment was stopped. Twenty cases were discharged during the year—14 of them improved and 6 not improved; among those discharged improved were some who could quite well assist in their own maintenance while living amongst relatives or friends. During the year 19 cases died; the death rate to the total number under treatment for the year was 3.9 per cent.; 4 of the deaths were due to epilepsy, an abnormally high percentage for this disease, and 2 were due to tuberculosis, which was an exceptionally low number; influenza was the cause of 2 deaths, and the indirect cause of 2 others.

Correspondence.

CLAYDEN v. WOODHILL.

SIR,—The letter on page 403 of your issue of August 26th deals with several points of great professional importance which the case in question brought out, but there are others which for a long time I have felt should be brought to the notice of your readers, and perhaps the closing of the fund serves as a good occasion for addressing you.

If I read rightly the official account of the proceedings, which owing to your kindness I was privileged to have at my disposal, I think I am right in concluding that the verdict against the defendant may be attributable to two things, of which one was that the court found that the fracture in question was not treated in the correct position. Now, it may be thought that I labour the point, but as such a view is so often put forward in other trials, and as so much of the textbook teaching tends to propagate the same line of thought, I would like to urge in the strongest possible way that there is no one universal routine position in which any given fracture must be put up, and that while it may be a fairly average truism of practical use for students and for teaching purposes that certain positions are as a rule necessarily desirable for the treatment of particular fractures, such a view is not fortified by so large an amount of truth as to be of value in a court of law. In the case at issue it was apparently laid down and admitted by the various experts that the limb should have been put up in abduction. If this is admitted (personally I doubt if the experts for the defence ought to have admitted this, though, as far as I read the evidence, it showed that the limb was put up in abduction) it is obvious that there are various degrees of abduction, and I should most strongly maintain that in any series of any particular fracture the degrees of abduction necessary to secure alignment, which is the sole object of abduction, vary considerably, and no one can form any opinion as to the degree of abduction desirable except the person who is treating the fracture. This is my point: That there is no one position in which all fractures of any one type must be treated; that each must be dealt with on its merits, and put in such a position as to secure alignment, of which the person who is treating it alone can be the judge. Incidentally it is quite an open question whether fractures of the upper third of the femur should be treated in abduction, as those who followed the papers by Major Lee of Fulham Military Hospital during the war will recall.

The second point which this case tends to emphasize, though no more than the majority of cases in which medical evidence is called for the plaintiff and for the defendant, is the hopelessness of the present method of employing medical experts on both sides of a case. Surely it is time that this practice, which scarcely advances medical prestige or makes for equity, should be discontinued, and it should be left to the court to demand and secure expert evidence if required. Having been compelled on several occasions myself to take part in similar farces for material gain I shall escape, I trust, any suspicion of casting mud at individual colleagues. It is the principle to which I object.—I am, etc.,

London, W., Sept. 6th.

C. H. FAGGE.

STERILIZATION OF MENTAL DEFECTIVES.

SIR,—In the correspondence on this subject some of the contributors write as if there was only one form of mental deficiency, whereas, as everyone knows, there are several varieties of it and it has several causes. Thus some cases are due to injury to the brain at birth, others to absence of

the thyroid gland, others to an arrested development of the brain, and so on. Sterilization is not going to prevent all forms of mental defect, and it is much to be doubted whether its adoption or the institution of State certificates of marriage would really do much to lessen the number of defectives born.

When I was doing out-patient work at the Hospital for Sick Children I took the trouble to inquire, so far as I could, into the family histories of a large number of defective children, and I was unable to satisfy myself that in the main their heredity differed in any way from that of normal children. It would seem that mental defect is a spot or unfavourable variation which may arise in perfectly normal families, just as physical defects do, and that each generation of average parents will produce its own crop of it just as it does of deformities such as hare-lip or club-foot. If this be so the diminution in the number of defectives which would result from the measures proposed would be so small as hardly to be worth while.—I am, etc.,

London, W., Sept. 10th.

ROBERT HUTCHISON.

SIR,—Sir G. Archdall Reid, in his letter published on August 26th, succinctly epitomizes some of the leading facts of heredity. The majority of people have very little knowledge of the traits and characteristics of their ancestors; many have only a vague remembrance of their grandparents. It only shows how difficult it is to formulate any definite facts on heredity. When we remember that each of us has four grandparents, sixteen great-grandparents, and so on, it goes to prove how intimate is the relationship between the human family. By this hypothesis it is possible to demonstrate that one's own ancestors exceeded the whole population by going back some generations.

There are certain facts in heredity that appear fairly constant, and one of these is the transmission of various forms of eye defects through apparently healthy females to the male offspring. Dr. W. M. Ash, in the *BRITISH MEDICAL JOURNAL* of April 8th, gives an account of an interesting family history through three generations of hereditary microphthalmia. Dr. Moriet, as recorded in No. 264, *EPITOME OF THE JOURNAL*, March 18th, mentions the case of a family afflicted with hereditary retrolental neovascularization ending in blindness who reside in a sparsely populated district in Western Australia. At the present moment there are seventeen unmarried girls in this particular family. From one union twelve entirely distinct families have become affected.

In each of the foregoing family histories the females are perfectly healthy and free of any defect, yet practically all the males are more or less blind. Naturally, Dr. Moriet feels some alarm as to the result of any of these seventeen girls marrying and having children, especially in such a sparsely populated country as Western Australia. Again at Bandera, a town in Texas, U.S.A., many of the inhabitants are possessed of twelve fingers and twelve toes. It has been stated that a member of the nobility has a defect in one of his fingers (as well as some of his relatives). The vault of one of his ancestors was opened, and a similar defect was found in the hand of the skeleton, who had been buried a few hundred years ago. Whether these defects were transmitted through the female is not quite clear. They are evidently problems in variation, belonging to the spontaneous form.

With regard to the defective eye families, a point of interest is, How did these defects originally arise? There must be cases of microphthalmia and hereditary retrolental neovascularization distributed, not only over this country and Australia, but throughout the world. Had they all a common ancestral origin—a sport of nature?

Germ cells, whether they be those of mammals, fishes, reptiles, or even plants, are very much alike so far as we are able to observe; yet profound changes take place in their development. According to Major Leonard Darwin these changes and developments are attributable to what he describes as the mnemonic theory of cellular growth, and no doubt if it were possible to solve this problem it would produce the most profound changes in this world as we know it, and life and existence would be different.

In dealing with such families with such defects of the eye sterilization may possibly act in keeping them under control. Unfortunately there does not appear to be an absolutely certain way of producing sterilization. Women who have had Caesarean section performed have also had a sterilizing operation done at the same time, and have been given medical certificates guaranteeing them from ever becoming pregnant again. In a few months' time they have turned up again

well advanced in pregnancy. Evidently we have still something to learn on this subject, although a surgeon has recently claimed success by tying the Fallopian tubes themselves in knots.—I am, etc.,

Plymouth, Sept. 2nd.

J. S. PEARSE.

SIR,—There are five and a half millions of school children in England, of which 1 per cent. is the expectancy of mental defectives, so that the 12,000 for which Dr. Gibbons says we are taxed is but a small part of the 55,000 that exist of persons at school age—say of 5 to 14 years. The school medical service no doubt affords a focus of preventive action for the benefit of humanity in the long run, but practically considered the prevention of mental defect by any action whatever would be very intricate and difficult owing to the unending connexions and ramifications of the hereditary lines, and the impossibility of following out the hereditary connexions. To lessen the numerical occurrence of mental defect may be a possibility which a persistent effort extending through a couple of generations would greatly enhance, but to remove the element of recurrence is probably as impossible as to deprive the sea of herrings by fishing. A sufficiently long period of neglect would result in the return to the old state. It would not suffice to limit the effort to England; it would have to be world-wide.—I am, etc.,

Cheltenham, Sept. 9th.

J. H. GARRETT.

THE ETIOLOGY OF GOITRE.

SIR,—In the BRITISH MEDICAL JOURNAL of February 4th, 1922, is an article by McCarrison on fats in relation to goitre. On it I would offer some suggestions which might possibly throw some light on the subject and modify the reading of the results of the experiments. McCarrison in his work on goitre has not stressed the important part played by calcium.

Goitre and calcium have such an obvious relationship that no treatise on goitre can be complete unless this point is given its adequate place in the roll of thyroid enlargements. I have dealt with this point in an article in the *New York Medical Journal* (April 5th, 1922), but will make use of such points as have bearing on these experiments. It has long been recognized that the viscosity of the thyroid secretion varies immensely, and this largely depends on its iodine content. In the limestone districts of Switzerland and Derbyshire large goitres containing thick colloid are usual. Analysis has shown this colloid to be poor in iodine. Such goitres vanish under the use of iodine or thyroid extract rich in iodine. The vesicles in a case of Graves's disease or thyrotoxic goitre are usually found empty or their colloid thin. The iodine content of such colloid has been shown to be rich in iodine, and the giving of iodine in these cases aggravates the condition. Colloids in the majority of cases owe their rigidity to the presence of calcium, which is balanced by iodine. Excess of iodine liquefies a gel, the addition of more calcium causes it to regain its rigidity. Professor Kendall of the Mayo Clinic states that there is no calcium in the thyroid colloid, but as has been said large goitres in the limestone districts of Switzerland and Derbyshire with thick colloid vanish under the use of iodine. With this balancing of calcium and iodine in colloids it can readily be understood that with an excessive calcium intake and an actual or relative deficiency of iodine the body colloids would tend to an increased rigidity, even if the kidneys were excreting calcium normally. The calcium picking up the available iodine would prevent it combining with the colloids, as is well illustrated by the reduced rigidity of body colloids in myxoedema when thyroxin or thyroid extract rich in iodine is given. These and many other factors lead one to the conclusion that calcium and iodine are intimately connected in the thyroid metabolism, and that each plays its part in the production of goitre.

The next question to consider is the absorption of calcium. In milk we have a marked illustration of the relationship between fats and calcium, also an example of the enormous amount of calcium relatively necessary to the human body. We have been struck repeatedly when one case of goitre appears in a family all of whom are subjected to the same conditions, including tonsillar infections, that the individual affected took no milk. It must be quite obvious that the calcium soaps formed from milk cause no trouble, yet when butter is given trouble arises. The solubility of different soaps varies, some producing a more soluble soap than others. Owing to the unsaturated condition of its fats the soap formed with cod-liver oil exceeds all others in its properties of solubility. 6 times protracted diarrhoea is set up by insoluble soaps

irritating the bowels. It is claimed by some authorities that cod-liver oil contains bile; if so, the presence of lecithin and cholesterol would materially help in breaking down the soaps formed from these fats.

Pigeons as well as tadpoles normally take very little fat and their powers of dealing with it will not be of a very high order. As we know from experience that human beings at times are unable to break down calcium soaps, it can readily be conceived that pigeons and tadpoles would likewise fail if that mechanism was taxed beyond its power. Soaps formed from the fatty acids of butter and oleic acid will be broken down with far greater difficulty than those formed from cod-liver oil. The solubility of soaps is due to the bile action, depending chiefly on the presence of lecithin and cholesterol. Starling says: "If the reaction be alkaline the alkali will combine with the fatty acids to form soaps. Analysis of the content of the gut after a fatty meal shows that the greater proportion of the fats are present as a mixture of fatty acids and soaps, the amount of these substances compared with the unchanged fats increasing as we descend the gut." We must deduce from this that fat taken above normal requirements will form soaps with the fatty acids combining with all the calcium and other alkalis present; this may well lead to calcium starvation. To explain the action of the iodine in benefiting goitres in the presence of fats, I may suggest that the iodine combines with the calcium to form calcium iodide; the calcium having such a close affinity for iodine would combine with that in preference to combining with the fatty acids, and so make some calcium available to the system. This, to some extent, is borne out by the type of goitre produced, as in no case was there a tendency to a retention of colloid, as is seen in the Swiss and Derbyshire goitres, but a type of goitre was produced of the thyrotoxic kind yorging on that found in Graves's disease in which there is either an excess of iodine or a deficiency of calcium, practically resulting in the same thing. In support of the view of the power possessed by cod-liver oil in carrying calcium into the system, I will refer to the work of Drs. Park and Howard,¹ who confined their attentions to the influence of cod-liver oil in rickets; their results were more definite than those of Phemister and his colleagues. The changes discoverable by radiographic means began four to five weeks after the commencement of treatment. The first evidence of repair was a line due to the deposition of calcium, which appeared between the extremity of the shaft and the centre of ossification in the epiphysis. The line became thicker and gradually spread so that the cartilage in the transitional zone became transformed into bone and infiltrated with lime. The calcium was so deposited that the end of the shaft assumed the appearance of a cup or crater embracing the nucleus of ossification. With a view to assisting the absorption of calcium I have recommended the use of bile salts.² At the same time I was evolving a method for testing small quantities of calcium in the blood, which was read before the Royal Society of Melbourne.³

The results of my experiments and the work of others led me to the conclusion that it was hopeless to look for any deficiency of calcium in the blood, as a certain proportion of calcium is necessary for the life of the individual; anything above is rapidly excreted, and anything below means death; to maintain this amount constant the supplies in the tissues and bones are called upon. This can be seen in animals put on a calcium-free diet, the epiphyseal junctions showing very marked increase of vascularity, suggesting a robbing of calcium from the bones. The same thing obtains when large doses of thyroid extract are given to rabbits; this strengthens the contention that in all cases of overactivity of the thyroid there is increased calcium output, very obvious in tuberculous, and accounting for the liability to haemorrhage in these thyrotoxic cases. This can always be corrected by these thyrotoxic cases. The haemorrhagic tendency exists in spite of the fact that no appreciable diminution of the calcium content of the blood is found. Those who have to remove infected tonsils in these cases are well aware of its value. This opens up the question whether although calcium may be present in sufficient quantities it may not be in the right combination or colloidal form.

As to the part possibly played by the onion, it is to be noted that the essential oils of garlic and onions have a very powerful bactericidal action, and so may have a very decided effect in eliminating the cause of thyroid enlargement.

Early in 1915 I began to see the relation between focal infections and goitre, and in March began to treat the condition by their removal, about the same time as Rupert Farrant was coming to the same conclusions at the other side of the world. Since then I have never seen any goitre without focal infection, and by removal and other treatment I have been able to deal satisfactorily with all my cases, only failing in those in which I was not able to remove the infection. Whilst fully recognizing the importance of bowel infection in endemic goitre, I would like to say that I have never seen a case in Australia. Since McCarrison's work was published many medical men have been trying to cure goitres with intestinal antiseptics where there was an obvious infection of the tonsils. In nearly all acute infections, and most others, there are signs of an overactive thyroid, irrespective of any enlargement, as shown by the signs of increased nervousness, tachycardia, and tremor. In all such cases there is a tendency to thinning of the colloid; those symptoms will predominate in districts poor in calcium or rich in iodine. In districts rich in calcium or poor in iodine infections will tend to produce a colloid which is too rigid to pass into the circulation, and will therefore accumulate in the vesicles; if any symptoms are associated they will be those of deficient thyroid activity. One must view the normal colloid as being of such rigidity as to pass into the circulation when a call is sent. If it is too rigid it will not pass but accumulate; if too thin it will pass continuously into the system. With these views in mind I cannot help coming to the conclusion that the part played by the fat in the production of goitre is only a link in the chain of calcium absorption or starvation.—I am, etc.,

SYDNEY PERN, M.R.C.S., L.R.C.P.Lond.

Melbourne, Victoria, July 24th.

BONE GRAFTING AND THE CIRCULAR MOTOR SAW.

SIR,—In his article on the treatment of spinal caries by bone grafting (BRITISH MEDICAL JOURNAL, July 15th, p. 73) Sir Henry Gray discusses the question of how the graft should be cut, and I fear that, however satisfactory he has found his method, a rather croneous impression is given regarding the use of the circular motor saw. In my opinion the Albee outfit is a great acquisition to a surgeon's set of tools. The long experience of Albee and the large number of cases successfully treated by him cannot be lightly set aside. His x-ray proofs are as fine as may be seen anywhere.

These results have been obtained by operation where the circular motor saw has been used. Therefore, the destruction of the osteoblasts in the graft, so cut, does not occur. This certainly has been my own experience, and I maintain that the frictional heat generated by the rapid circular saw is not so great as might be imagined. It has been shown that a saw working at 250 revolutions a minute generates only 4 degrees less heat than one at 6,000. Then, again, it must always be remembered that it is only fair to the instrument that a sharp blade should be used. The use of a cold saline solution drip is indicated in cases where thick adult cortex is cut, and all spluttering of saline, blood, etc., may be prevented by the "guard" attachment to the "shell" of the motor.

It is many years now since I employed an exactly similar method to that described by Sir Henry Gray—namely, the drilling of holes along the line of section of the graft from the shaft of bone, in order to prevent splintering by the osteotome, which usually occurs if such drill holes are not made, and which may occur even when they are made.

There is no instrument that can cut such a perfect graft as the circular motor saw. Again, there is no comparison between the old and new methods when speed is taken into consideration. In bone-grafting operations, particularly those required for spinal caries, speed is an important factor. A very large number of such cases occur in quite young children, who bear prolonged general anaesthesia badly. There are few of us who do not know how expert Sir Henry Gray is in the use of local anaesthesia; but I am sure that the bulk of such operations in very young subjects are performed by the majority of less expert surgeons under a general anaesthetic. There, speed is an important factor.

There is another large area in the field of bone surgery where the question of bone grafting is very important—namely, the treatment of delayed union of fractures of the long bones. It is a matter of common experience to find now

and again a case in which bone repair at the seat of fracture is either long delayed or is non-existent.

Such cases may be due to the interposition of muscle, etc., between the broken ends, but there are others where no recognizable displaced tissue has been interposed, and it is assumed that the delay is due to a disturbance of the normal metabolism. This is frequently admitted; in part at least, by the administration of thyroid extract to the patient in the hope of stimulating in one or more directions the metabolic changes necessary for bone repair.

These are just the cases where, if Sir Henry Gray's contention is correct that considerable damage is inflicted upon the osteoblasts of the graft by the frictional heat of the motor saw, one would expect a large percentage of failures. I do not possess the experience of a Gray nor an Albee in bone surgery, but I have treated such cases by the inlay bone graft, cases in which I had great difficulty to account for the delayed union. I have found that the Albee graft does very well indeed, especially if it is steadied laterally by thin bony wedges placed along the sides of the graft bed, coupled with the use of retaining strands of kangaroo tendon to prevent movement of the graft towards or from the medullary cavity of the bone under repair. It is to be remembered that we are cutting, not the thin delicate tibial shaft of the young child, but the dense cortex of the adult bone where the frictional heat of the saw should be almost at a maximum. Yet they do well—the grafts neither disappear nor become sequestra.—I am, etc.,

GEORGE ROBERTSON, F.R.C.S. Edin.,
Honorary Surgeon, Danfermline and West of
Fife Hospital.

August 31st.

MUSCLE NECROSIS.

SIR,—I read with interest the case of muscle necrosis due to intramuscular injection of quinine reported in a recent issue of the JOURNAL. I saw several cases while attached to No. 1 General Hospital, Wynberg, and was so impressed with the serious results of these cases that I ceased to give injections beneath the fascia, and for eighteen months treated my cases by subcutaneous injections with excellent results; in about six cases slight necrosis occurred at the site of injection, which soon healed.

Briefly, the advantages obtained by quinine given this way rather than orally are:

(1) It can be given when, owing to vomiting, quinine cannot be given by the mouth. (2) The quinine is present in the blood while the malaria parasite is free in that fluid. (3) It relieves quickly muscular pains present in some cases of malaria. (4) In anaemic and debilitated subjects apparently large doses of quinine taken by mouth are not absorbed. (5) It acts quickly and certainly (a big advantage in cachectic patients): six to eight injections of from 5 to 10 grains, and the patient is convalescent.

At the request of Colonel v. Zyl I read a paper before the Cape Town Branch of the British Medical Association, in which temperature charts of over 100 cases treated by injections were handed round; the paper was published in the *South African Medical Record*, July, 1918.

My object in writing this letter is to warn men new to treatment of malaria of the danger of intramuscular injections, and to assure them that the subcutaneous method is just as efficacious without the risk of muscle necrosis, which I am sure is not due to faulty technique but to the action of quinine in some patients who appear very susceptible to the drug.—I am, etc.,

Barville, U.S. Africa. Aug. 20th.

NEW REGULATIONS FOR TRAINING FOR THE D.P.H.

SIR,—A typographical error has crept into the otherwise very accurate report of the Public Health Section at the Glasgow Annual Meeting and of the arrangements made for the teaching of public health in this city and port (BRITISH MEDICAL JOURNAL, August 26th, p. 364).

Section 1 of the syllabus reads: "Interviews with the Ministry of Health as often as possible"; obviously this should read: "Interviews with the Medical Officer of Health as often as possible."—I am, etc.,

E. W. HOPE,
Liverpool, Sept. 7th.
Medical Officer of Health.

SIGHT-TESTING OPTICIANS.

Sir,—The letter from Mr. Parkinson Higham (September 9th, p. 489) advocating the giving of a charter to opticians in order that they may be bound down to a strict code of etiquette is a very dangerous one. The same argument was used with regard to midwives, and the result is that midwives are now in an established position, registered by the State, and have taken away from medical men the majority of midwifery cases. Before they were recognized the public knew that they were taking a certain risk in going to midwives: now they look upon them as able to do their work as well as a medical man. You may give a man a diploma and register him, but you cannot bind him down to carry out any rules and regulations.

The supply of spectacles by opticians is a scandal, and in many cases a swindle. It is a purely business transaction, and the more advertisements appear in the papers that assert the wonderful knowledge of eyesight possessed by these opticians, and the more extravagant their claims, the greater their takings and the greater the harm they do.

The trade of the optician must be very lucrative indeed. The charges they often make for spectacles would cover a medical man's fee as well as the cost price of the spectacles at a wholesale house. It is astonishing to see the enormous number of people who wear spectacles nowadays. And yet those who know something about eye diseases all acknowledge that it is dangerous to prescribe spectacles without knowing something about diseases of the eye. Retinoscopy is also essential in most cases. But I am afraid that it is the fault of the medical profession that opticians have attained the position they have already. There are many medical men in general practice who would do refractions for a fee of half a guinea, but the public do not know of them. The result is that the work is done by ophthalmic surgeons only, whose fee is prohibitive to many people. Consequently the public go to opticians. A medical man in general practice cannot advertise that he does refraction work, and the public do not know of his existence. There also seems to be a disinclination on the part of many practitioners to send their patients to another for refraction work. I wonder whether a medical man who set himself up to do refraction work at a fee such as mentioned above would get the support of his professional colleagues, and how would it be possible for him to let the public know that he does this work? What would be a suitable title for him to adopt? How would it be for him to put on his plate "Ophthalmic Surgeon," "Refraction work only," or something of this kind? If he puts "Eye testing" or "Spectacles prescribed" he runs a risk of being mistaken for an optician. Can you suggest a title, Mr. Editor?—I am, etc.,

Hastings, Sept. 11th.

ARTHUR E. LARKING, M.D.

Obituary.

SIR CHARLES RYALL, C.B.E., F.R.C.S.,

Senior Surgeon to the Cancer Hospital, London, and to the
Bolingbroke Hospital.

THE announcement of Sir Charles Ryall's sudden death on September 5th while on holiday at Dornoch was an overwhelming shock to his many friends, especially to those who only a few weeks previously had seen him in London vigorous, alert, and cheerful as he always was. The very morning of his death he wrote to his secretary in London saying that he had never felt better, and arranging that a party of friends be asked to shoot with him in Hertfordshire next week. An anginal attack while at the luncheon table—and within a few moments all was over.

Born in 1869, Charles Ryall traced his descent from one of Cromwell's officers who settled in Ireland at the termination of the Irish wars, and was the son of E. C. Ryall, who served through the Crimea and the Indian Mutiny in the A.M.D. After obtaining his medical education at Dublin University Ryall spent a year or two in post-graduate work in Paris and London, and was then appointed house-surgeon to the Cancer Hospital. While holding this post he became F.R.C.S., and so impressed were the authorities of the hospital by his sagacity, energy, and ability that he had the unusual experience of being elected to the honorary staff while a house-surgeon. This was the starting point of

Ryall's successful career. He became surgeon to the Cancer Hospital at a time critical in its fortunes, and it is impossible to overestimate the far-reaching influence he exercised. Aseptic surgery had just made its appearance, and his tact, skill, and sound judgement played an all-important part in placing the work of the hospital in the position it occupies to-day.

The Cancer Hospital was always foremost in his thoughts; he was devoted to its interests, and his far-seeing and statesmanlike views were of untold value to his colleagues and to the house committee. But there were many other spheres of activity that claimed Ryall's attention. The Lock, the Gordon, and the Bolingbroke Hospitals all received many years of ungrudging service. From the two former he retired some time ago, but at the time of his death he was senior surgeon to both the Bolingbroke and the Cancer. These were the clinical centres where Ryall built up a reputation for clinical acumen, technical dexterity, and sound judgement which earned for him the respect and esteem of his fellow surgeons and, in fact, of the whole of his professional brethren.

The commanding position that Ryall had come to occupy was shown in unmistakable manner by the overwhelming voting which returned him at the top of the poll on his election to the Council of the Royal College of Surgeons. This was a notable—indeed, an unprecedented—achievement for a man who was not on the staff of a teaching hospital, and who could not, therefore, command the solid support ensured by such a position. Ryall naturally came to be regarded as the representative and champion of the special and non-teaching hospitals, and fully did he justify the confidence that had been placed in him.

Very soon after the outbreak of war, like so many others who found themselves over the age acceptable to our military authorities, Ryall was at work for the Belgians; but, following upon the German advance, he had to return to London, and at once became engaged in every kind of war activity. Overburdened with surgical work at his own hospitals owing to the absence of the younger men, he yet made time to carry out much useful work at King George V Hospital, the Countess of Camarvon's Hospital, and many of the smaller officers' hospitals that sprang into being all over London. A little later in the war he was able to render services of the greatest importance to the nation, for, with the institution of compulsory military service, the need for just such men as Ryall was at once manifest. As a member of the Special Medical Appeal Board, the Advisory Medical Board for National Service, and many other similar bodies, he was exactly in his element. His great tact, unerring judgement, and wise discretion rendered him absolutely invaluable, and had he lived it is certain that he would have been called upon to carry out still more important duties in this sort of capacity.

Wide interests and a far too busy life left little time for writing, and Ryall's contributions to surgical literature were few, but what he did write stood the test of time. Almost his earliest observation was the danger of cell implantation during the course of cancer operations, and it has had an important influence in the surgery of malignant disease. Member of the International Surgical Society and Organizing Secretary for next year's congress, President of the Sub-section of Proctology of the Royal Society of Medicine, member of the Committee on the Physical Education of Girls, Past-Master of his Masonic Lodge (No. 2000), and chairman of one of the subcommittees of the Council of the College of Surgeons—it is impossible to realize how Ryall got through it all. He never spared himself—an emergency operation, a firesome committee, a medical meeting, a lecture by a friend or colleague, he was always there and always the same—cheery, optimistic, friendly.

No picture of Ryall would be complete without some reference to his life outside his professional work. He was a great sportsman, and whether it was shooting, fishing, golf, or mountaineering he showed the same eager spirit and the same boy-like aptitude for enjoyment that was such a lovable trait in his character and so endeared him to his friends. Ryall had a genius for friendship. There is no one who had more friends and no one who deserved more. Simple, modest, unassuming, he inspired loyalty and affection in all who came in contact with him. Those of us who were privileged to know him intimately had a regard for him not easily put in words—to each and every one of us he was wise counsellor, genial companion, and closest friend, and we loved him. "To be a prop of strength to a human soul in a moment of weakness is to know the glory of life." C. R.

We are indebted to Sir JAMES GALLOWAY for the following appreciation: The intelligence of the sudden death of Sir Charles Ryall must have come as a shock to his many friends and colleagues. We were on vacation as he was, and the bad news struck us on casually glancing over the columns of the daily paper. Charles Ryall's generous and sympathetic nature made him a welcome friend in a wide circle, and those who had the advantage of knowing him valued his good judgement and broad sympathies as well as his bright and friendly temperament. His qualities of sound reasoning and kindly judgement were well known to his professional brethren, and were specially well observed and indeed developed during the years of the war, when he acted as Medical Assessor to the appeal tribunals in close association with the Local Government Board and the Ministry of National Service. Ryall was the right man in the right place to fulfil the duties required at that difficult and critical time. The cases of those seeking exemption from or mitigation of military service were numerous, difficult, and frequently vexatious; but however vexatious and however ingenious were the difficulties raised Ryall would judiciously and sympathetically deal with the multifarious objections and also with the many true difficulties. There can be no doubt in the minds of those who worked in closest association with Ryall at that time that the work during 1917 and 1918 tried him severely, both mentally and physically. His premature departure affects many, but in a very special way those whose friendship with Charles Ryall became a very intimate and living thing during the difficult days of the war.

Dr. ARCHIBALD LEITCH writes: The outstanding quality that endears a man to his fellows, that lights up the eyes with pleasure at his coming and keeps green memories when he passes, is goodness of heart, and if over a man had a heart of gold it was Charles Ryall. His radiated kindness: he was for ever doing kind and thoughtful deeds. Many a one he helped who was down and out. Many a young man struggling upwards, who perhaps knew nothing of his influence unostentatiously and even surreptitiously exerted, had him to thank largely for success. However successful a man may be there come times when he needs a friend to give him confidence and to stand by his side in crises, and Charles Ryall was always ready. He thought and said the best of other people: no tinge of acerbity, envy, or malice coloured his criticism; he had no enemies, and all his acquaintances were his friends. We, his colleagues, loved him. With his wide sympathy and understanding he made our interests and difficulties his very own. His wonderfully sound judgement, operative dexterity, and quick wit and resource in emergencies made him a surgeon's surgeon, so that when illness affected us or our families he was the one to whom we first turned for advice and comfort. The well-merited honours that came to him were to us personal pleasures. He sacrificed himself during the war doing the work of a dozen men; it broke his health and left him a tired man, but his tireless soul permitted him no rest from the calls of duty. His life was happy and good. Beyond doubt there was written under the records of his stewardship "good and faithful servant" when this last sudden poignant call took our trusty and lovable friend away.

A largely attended funeral service was held on September 9th at Christ Church, Marylebone, and in the presence of sorrowing relatives, friends, and colleagues the interment took place at Kensal Green. A devoted wife is left to mourn his loss, and deep sympathy is felt for her in her sorrow.

J. A. MANSELL MOULLIN, M.B., M.R.C.P.,
Consulting Physician, Hospital for Women, Soho Square.

Dr. JAMES ALFRED MANSELL MOULLIN, who died on August 14th, was educated at Oxford University, Dublin, and St. Thomas's Hospital. He graduated B.A. Oxon. in 1872, M.A. in 1875, and M.B. in 1877. In the following year he obtained the membership of the Royal College of Physicians of London. He was associated with the Soho Hospital for Women for some forty years, and took a very considerable part in the reorganization of its work. At the time of his death he held the post of consulting physician to that institution. He was also in succession assistant physician, physician, and consulting physician for diseases of women at the West London Hospital. He was a former president and treasurer of the British Gynaecological Society before it became amalgamated with the Royal Society of Medicine.

A colleague writes: Mansell Moullin's interests were almost exclusively confined to gynaecology, and he cared little for midwifery. As a surgeon he was fearless and dexterous and very much enjoyed his operative work. He was the author of many contributions to gynaecological literature. In public he had a shy and retiring manner and was from this cause perhaps little known by the majority of his colleagues. Those with whom he was thrown professionally he was always courteous and considerate. One of his recreations was shooting, to which he looked forward each year with great keenness and about which he was ever more than willing to talk.

We regret to record the death, after a prolonged illness, of Dr. ROBERT WYNE-STANLEY WALKER, of St. Heliers, Jersey, which took place at the residence of his father, Glenn Hall, Leicester, at the age of 39. Dr. Walker was educated at Cambridge University and University College, London. He graduated M.A., M.B., B.Ch. in 1908, and proceeded M.D. in 1910, being awarded the Raymond Horton-Smith prize for his M.D. thesis on congenital heart disease. After holding resident posts in University College Hospital, the Hospital for Women, Soho, and the Great Northern Hospital, he went into practice in Jersey, where he was appointed honorary surgeon to the Jersey Dispensary and Infirmary. He was honorary secretary and treasurer of the Jersey Division of the British Medical Association. During the war Dr. Walker joined the R.A.M.C. and went out to Salonica, and on his service he contracted tuberculosis. The strain of medical practice during the influenza epidemic a few years ago aggravated his tuberculous trouble, and of recent years he had spent the winters in Switzerland and the summer between his home in Jersey and Glenn. Dr. Walker made several contributions to medical literature. His many friends will regret the untimely end to what had promised to be a brilliant career.

JOHN ANDREW TURNER, M.D. Edin., D.P.H. Camb., late health officer of Bombay, died recently in London. He was educated at Edinburgh, and after qualifying turned his attention to sanitary work. His first appointment in this line was H.O. of a district of Leicestershire and Rutland, and subsequently he became M.O.H. for Hertfordshire. From this appointment he proceeded to Bombay in the year 1901. Plague broke out in that city in the latter part of 1896, so that on his arrival the H.O. was called upon to face the problem of starting remedial measures, very little having been done in the four years previous. At that time the epidemiology of the disease was very ill understood, so that it was no light task that the H.O. had to face. The problem of ridding huge oriental cities of this disease is still awaiting solution. At the same time Bombay owes much to Dr. Turner for many improvements in sanitation and housing. He paid particular attention to tuberculosis and venereal disease in the later part of his career and went in for a vigorous campaign of propaganda against both of these diseases, leagues of lay workers and local practitioners being formed to assist. He was awarded the C.I.E. shortly before his retirement. On settling in London he obtained a temporary post under the Ministry of Health, but he vacated this some months before his death.

We regret to record the death from drowning, while on holiday in Anglesey, of Dr. ARTHUR HOWARD of Macclesfield. While bathing with a large party in a rough sea at Rhydwen he and several others got into difficulties, but although his companions were rescued Dr. Howard was carried out on sight by the waves, and his body was not recovered until some hours later. He received his medical education at Owens College, Manchester, and graduated M.B., Ch.B. Viet. in 1903. He had held resident appointments at the Kent and Canterbury Hospital and Northampton General Hospital and was formerly resident superintendent of the Borough Hospital, Birkenhead.

The death took place on September 1st, at Llandudno, of Dr. DAVID LLEWELLYN DAVIES, of Neath, in his 77th year. He had been visiting North Wales and fell and fractured a leg at the Swallow Falls, whence he was conveyed to a nursing home in Llandudno. Dr. Davies was educated at the University of Glasgow, and graduated M.B. C.M. in 1874. He was medical officer to the Neath Union Workhouse, a justice of the peace, and held many other public appointments in the district, where he carried on a large practice and was deservedly popular.

The death took place recently at Paisley Royal Infirmary of Dr. ALEXANDER MACLEAN, who was for fourteen years a member of the medical staff of the Glasgow Public Health Department. Dr. Maclean was educated at Glasgow University, where he graduated M.B., Ch.B. in 1902; he took the D.P.H. of the Royal Colleges of Physicians and Surgeons of Edinburgh in 1903. He was formerly senior assistant medical officer at the Western District Hospital, Glasgow, and on appointment to the Public Health Department he became assistant bacteriologist. He devoted special attention to the relation of housing conditions to disease, and for a number of years held a special post as junior medical officer for housing purposes; in 1920 he was transferred to the northern division of the city as a clinical medical officer.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE next examinations for medical and surgical degrees will be of October. Parts I and II of the First begin on October 3rd, and Part III on pharmacology and general pathology) of the Second M.B. Examination will begin on October 2nd.

SOCIETY OF APOTHECARIES OF LONDON.

THE Diploma of the Society has been granted to the following candidates entitling them to practise medicine, surgery, and midwifery: E. E. Briant, A. Gugenheimer, F. D. Howitt, and W. J. Verheyden.

The Services.

DEATHS IN THE SERVICES.

Surgeon Rear Admiral George Trevor Collingwood, C.B., R.N. (retired), died at King Edward's Convalescent Home, Osborne, Isle of Wight, on September 2nd. He was born in 1853, educated at the M.R.C.S. and L.R.C.P. London, in the following year. He joined the Royal Navy in 1873, and retired in 1921. As surgeon of the *Hydgon* he served in the Naval Brigade landed at Bathurst, on the Gambia river, in February, 1894, for the punishment of Fodi Silah, a slave-raiding chief; in September, 1894, in the expedition against the chief Nanni, on the Benue river, and was present at the capture of Brohemi, the chief's stronghold, in September, 1894; and in the expedition against King Koko, of Nimby, on the Brass river, in February, 1895, was mentioned in dispatches, and received the Africa General Service medal, with three clasps. From 1903 to 1912 he was P.M.O. at the Royal Naval College, Osborne. In the recent great war he served in the Dardanelles, on H.M.S. *Inflexible*, and afterwards in charge of the naval hospital ship *Soudan*; and after the war was appointed head of the naval hospital at Malta. He received the Sir Gilbert Blane gold medal in 1909, the M.V.O. in 1910, on the occasion of King George's visit to Osborne, and the C.B. in 1919.

Inspector-General Henry MacDonnell, C.B., R.N. (retired), died at Southsea on September 2nd, aged 83. He was born in 1839, the son of William MacDonnell, Esq., of Dublin, educated in that city, and, after taking the L.R.C.S.I. in 1860 and the L.K.Q.C.P. in 1861, entered the navy as assistant surgeon in 1861. He attained the rank of inspector-general in 1897 and retired in 1899. He was in charge of Malta Naval Hospital from 1893 to 1896, Chatham Hospital 1896-97, and Haslar Hospital 1898-99. As fleet surgeon of H.M.S. *Invincible* he served at the bombardment of Alexandria on July 11th, 1882, and during the Egyptian war, receiving the medal with a clasp and the Khedive's bronze star. He was granted the C.B. at Queen Victoria's diamond jubilee in 1897, also the jubilee medal. In 1886 he married Frances Alice, daughter of the late Sir William R. Holmes, Consular Service, of Kilkenny, Ireland.

Colonel Edward Horace Lynden Lynden-Bell, C.B., A.M.S. (retired), died in the Officers' Hospital, Millbank, on September 1st, aged 63. He was born on December 18th, 1858, the son of Major-General T. Lynden-Bell, of Brook Hill, co. Wexford, and educated at Edinburgh University, where he graduated as M.B. and C.M. in 1882. Entering the R.A.M.C. as surgeon on August 4th, 1883, he attained the rank of lieutenant-colonel after twenty years and colonel on September 19th, 1912, retiring on December 26th, 1917. From 1912 to 1914, and again in 1917, he held the post of D.D.M.S. London district. He served in the Burma campaign in 1885-89, receiving the Indian frontier medal with two clasps; and in the war of 1914-18, when he was mentioned in dispatches in the *London Gazette* of October 19th, 1914. He received the C.B. in 1915, and was appointed a Knight of Grace of the Order of St. John of Jerusalem in 1916.

Lieut.-Colonel Lewis Haywood, R.A.M.C. (retired), died at the Officers' Hospital, Brighton, on August 31st, after a long illness, which dated from the South African war. He was born on August 10th, 1857, educated at Aberdeen, where he graduated as M.B. and C.M. in 1880, and entered the army as surgeon on February 4th, 1881. His name was then Lewis Haywood Truefitt, but he subsequently dropped the surname. He attained the rank of lieutenant-colonel after twenty years' service, and retired on October 22nd, 1902. After his retirement he was employed at Scarborough in 1903-04, Aldershot 1905-07, and Lincoln in 1908-09; in 1909 he was appointed staff officer to the A.M.S., South Midland Division, R.A.M.C. (T.F.), and subsequently D.A.D.M.S. of that division. He served in the South African war in 1899-1901, and took part in the relief of Ladysmith, including action at Colenso, operations on Tugela Heights, action at Pieter's Hill, and operations in the Transvaal, including the action at Zidicatis Neck, was mentioned in dispatches in the *London Gazette* of February 8th, 1901, and received the Queen's medal with four clasps.

He attained the rank of lieutenant-colonel after twenty years' service, and retired on October 22nd, 1902. After his retirement he was employed at Scarborough in 1903-04, Aldershot 1905-07, and Lincoln in 1908-09; in 1909 he was appointed staff officer to the A.M.S., South Midland Division, R.A.M.C. (T.F.), and subsequently D.A.D.M.S. of that division. Medical News.

A POST-GRADUATE course will be held in medicine, surgery, and pathology at Addenbrooke's Hospital, Cambridge, from Monday, September 25th, to Saturday, September 30th. There will be a morning session from 11 a.m. to 1 p.m., and an afternoon session from 2 to 5 p.m. each day. The times have been so arranged as to enable as many as possible of those wishing to attend to carry on their practices at the same time. There will be no fees for the course. A dinner will be held on Tuesday, September 26th, at 7 p.m. A programme and further particulars can be obtained from the secretary to the staff, Addenbrooke's Hospital, Cambridge.

THE opening ceremony of the winter session at King's College Hospital Medical School, Denmark Hill, will be held at 2.45 p.m. on Tuesday, October 3rd. The introductory address will be given by Sir Herbert Jackson, K.B.E., F.R.S., with Viscount Hambleden in the chair. The annual dinner of past and present students will be held at 7 for 7.30 on the same day at the Café Royal, Regent Street, W., with Dr. Percy Lewis in the chair.

THE third annual lecture conference for welfare supervisors organized by the Industrial Welfare Society will be held at Balliol College, Oxford, from September 15th to 20th. This year the conference is open to both men and women, special arrangements having been made for the women delegates at Lady Margaret Hall. The Session will be opened by Mr. J. W. Pratt, M.P., Parliamentary Under-Secretary for Scotland. The programme will deal with such subjects as "Welfare under the Whitley principle," "The employment department: its functions and personnel," "Health, first aid, safety," Mr. Frank Hodges, Secretary of the Miners' Federation, will give an address on "Health and welfare in the mining industry," and Dr. H. M. Vernon, of the Industrial Fatigue Research Board, will speak on "Record keeping and statistics." Inquiries regarding the conference should be addressed to the Industrial Welfare Society, 51, Palace Street, Westminster, S.W.1.

SIX months' Courses of Lectures and Practical Instruction in Part I (Physics and Electro-Technics) and in Part II (Radiology and Electrology) for the Diploma in Medical Radiology and Electrology of the University of Cambridge will be given in London, beginning October 3rd, 1922, and in Cambridge and London, beginning January 9th, 1923, for examination at the end of the courses. For further particulars application should be made to Dr. Stanley Melville, 12, Stratford Place, London, W., or to Dr. F. S. Billington Seales, Medical Schools, Cambridge.

A COURSE of lectures on maternity and child welfare and school hygiene will be delivered at the Royal Institute of Public Health, Russell Square, London, during October, November, and December. Medical practitioners, medical students, health visitors, and others engaged in any form of public health service are invited to attend. The opening lecture on Wednesday, October 18th, at 4 p.m., will be given by Professor Louise McIlroy on the influence of ante-natal care upon infant mortality. Particulars may be obtained from the honorary secretaries at 37, Russell Square, W.C.1.

DURING the last twelve months 32,414 rats were destroyed in the docks and warehouses of the Port of London Authority, compared with 39,112 in the previous year.

DR. HUBERT WORK, Postmaster-General of the United States, and formerly President of the American Medical Association, was the guest of honour at a dinner given in Washington by the Panama Chargé d'Affaires, Señor Lefevre, in recognition of the co-operation of a committee of the American Medical Association appointed to act with the board of directors of the Gorgas Memorial.

AN interallied congress on cancer will be held at Strasbourg in the spring of 1923, when the following topics will be discussed: (1) Experimental production of cancer; (2) spontaneous and provoked reactions of the organism against cancer; (3) treatment of cancer of the breast by irradiation.

THE Russian Pirogoff Surgical Society of Petrograd has announced that the fifteenth Russian Surgical Congress will take place from September 24th to October 1st. The organization committee consists of the council of the society, of which Professor Grekow is president, associated with a number of other members of the society. The chief subjects for discussion will be: (1) the anatomy and pathology of the vascular system; (2) chronic ulcer of the stomach; (3) surgical complications of exanthematic and recurrent fever; (4) treatment of surgical tuberculosis.

AT the third annual convention of the Canadian Radiological Society, held recently at Winnipeg, Dr. Lewis J. Carter of Brandon, Manitoba, was elected president.

IT is announced by the United States Treasury that Dr. J. W. Scherechewsky, assistant surgeon-general, U.S. Public Health Service, has been commissioned to conduct an investigation into the cause of cancer; the headquarters of this investigation will be established in Boston.

IT is reported from Manila, according to the *Journal of the American Medical Association*, that numbers of "chiropractors" have recently arrived in the Philippine Islands from the United States. They have bought full-page advertisements in the local newspapers, claiming to cure almost every ailment, and they are attempting to get a bill submitted to the Legislature regulating the practice of "chiropractic" and to establish a chiropractic examining board for the Philippines.

THE leading educational institutions in eastern China are co-operating in a project to found a medical school in Shanghai. This proposal was abandoned last year by the China Board, but is now being revived with considerable assurance of success. The suggestion is to combine Chinese and American funds and build a union medical school, using St. John's medical department as a nucleus of the new school. The Women's Union Missionary Board has decided upon Shanghai as the best place to found a women's medical college, and is entering whole-heartedly into the present union scheme.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Ailology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

SHELTER LIFE FOR CHILDREN.

DR. WM. J. AITKEN QUINE (Chinley) writes: In reply to the inquiry from "Alpha" (p. 493) I may say that in my opinion shelter life for a 4 year old child in Derbyshire is perfectly feasible, provided that the feet are kept warm by a large, well-protected, hot-water bottle at night in cold weather. The climate is damp, more especially on the western slopes of the Pennines, but not foggy to any marked degree. On the other hand fog, when formed, is often very slowly dissipated from enclosed valleys such as that in which Buxton lies. The county health authorities provide a useful form of shelter for suitable tuberculosis cases, and evidence of the way in which open air life is adopted is to be found in the great reluctance of even small children to give them up and sleep indoors again.

EPIDEMIC STOMATITIS.

"CLOYBANK" asks for references to recent recorded cases of epidemic stomatitis in children. There have (he says) been three cases in one family in my practice, the chief features of which have been small ulcers of gums and lips, foul tongue, mild febrile reaction, and anorexia.

CERTIFYING FACTORY SURGEONS.

"J. E." asks what remuneration a certifying factory surgeon usually receives, and to whom an application should be made when a vacancy occurs. We have referred the question to a correspondent with special knowledge, and his reply is as follows:

Examination of Young Persons.—The Factory Act (Sec. 124) enables the employer and the surgeon to arrange the amount of fee or annual charge, and this is extensively done. In the absence of an agreement the remuneration must be by fixed scale, which allows, at present, 2s. 6d. per visit or, if more than two are examined, 1s. per head; mileage at the rate of 6d. per complete half mile after the first is to be added. For examination at the surgeons' rooms the fixed fee is 1s. per person.

Examinations under Regulations.—The scale is as above, and although nothing is said about mutual arrangements there is no reason why an employer cannot pay as much as he cares to.

Investigation of Accidental and other Poisonings and of Certain Industrial Diseases.—The fees, which are paid by the Home Office, are at the original rate fixed in 1844—namely, 3s., to cover a visit to the works, a visit to the patient and the report, with mileage as above.

Certificates under the Workmen's Compensation Act.—For examination and certificate 5s., with an extra 1s. for each mile or part travelled when the patient is visited. If an examination of the case has already been made under the Factory Act the fee is 1s. only, which, of course, means that the surgeon draws less for a double duty than for certifying under the Compensation Act alone. The fee is to be paid by the workman, but the employer frequently takes up this obligation.

When a vacancy occurs application should be made to the Chief Inspector of Factories, Home Office, Whitehall, London, S.W.1.

INCOME TAX.

"O. K. M." served with the Defence Force in 1921, as a result of which his civil income was reduced by £132, £42 through payment of fees to a lodgment plus £90 lost through inability to attend pensioners boards. What can he claim for this loss?

* * The payment of £42 can be charged as a professional expense, but as regards the loss through reduction of earnings no claim can be made; it is, of course, only the reduced amount of the earnings which count as receipts. Tax is legally due on the amount of the Defence Force pay.

"R. M. S." has this year been refused a deduction for the cost of purchasing medical textbooks and of subscribing to medical societies.

* * As we have often said before, we consider that expenses incurred in maintaining, as distinct from improving, a medical library are allowable as necessarily incurred in the performance of the duties of the office. We fail to see any distinction in principle between the expense incurred in maintaining, for example, a set of instruments in proper condition, with the cost of keeping up to a proper level the stock of professional knowledge.

"W. B." is in general practice and holds an appointment as administrator of a hospital. He has been refused a deduction for the expense of travelling between his professional premises and the hospital.

* * Some years ago the Board of Inland Revenue agreed that a hospital appointment need not be separately dealt with—that is, that a single assessment be made under Schedule D on the full earnings of the practice plus the appointment. We have not heard that this arrangement has been terminated, and assuming that it continues, "W. B." should apparently be assessed in one sum for all his earnings, in which case the expense is allowable as the case quoted refers only to an assessment under Schedule E.

"O. Y." asks: Has an inspector of taxes any right to demand the inspection of a bank pass book?

* * No. We must, however, add that if an assessment is made against which the taxpayer appeals, the Commissioners by whom the appeal is to be heard can require production of such evidence as they think fit, and confirm the assessment if this is not forthcoming.

LETTERS, NOTES, ETC.

GASTRO-JEJUNOSTOMY FOR PERFORATED GASTRIC AND DUODENAL ULCERS.

SIR JOHN O'CONNOR, K.B.E., M.D. (Senior Medical Officer, British Hospital, Buenos Aires) writes: May I beg to mention that personal (including some bitter) experience convinced me some years ago that, on this side of the Atlantic, the operation for closure of the perforation does not cure the ulcer, and compelled me to adopt the following plan of treatment: Close the perforation, keep the patient in bed for one month, on milk; then perform gastro-jejunostomy, repeat the rest in bed on milk diet (with or without an egg nog once or twice daily) for another thirty days, and follow by careful "gradual" feeding for one year. It is my profound belief that if, in cases of ulcer treated

by gastro-jejunostomy, one were to adhere to one month's rest of stomach and body and follow this by intelligent feeding for one year, we should hear nowadays much more about the virtues of gastro-enterostomy and a great deal less about the necessity for gastrectomy, which, by the way, produces another sore, which has to be dealt with by the natural factors of repair, and which I find sometimes passes into a condition of chronic ulceration, ending up also in cancer. The fact must not be ignored that the human cells have got to do the healing; given the general feeble power of cellular restitution which obviously must exist in everyone who has a chronic ulcer of the stomach, is there any reason to assume that the chances (omitting shock following operation) of cure are enhanced by the substitution of a huge anastomosis for a smaller chronic one, which at one time originated in a small acute lesion? I do not wish it to be inferred that, in some instances—particularly ulcers attended with a mass of chronic induration which in all probability is beyond the power of natural resolution, I advocate gastro-jejunostomy in preference to gastrectomy; I maintain that in cases where the latter is essential the former should be added so as to ensure an after-treatment which will correspond to the natural law of repair.

SPA TREATMENT FOR PHLEBITIS.

DR. CHARLES BOYCE (London, S.W.) writes with reference to the treatment of phlebitis and other venous ailments to draw attention to the benefit that may be derived from the thermal waters of Bagnoles de l'Orno, in Normandy, where a spa establishment was founded in 1718. The waters contain carbonic acid, silica, and salts of iron, calcium, magnesium, potassium, sodium and lithium, and are radio-active. They have gained considerable renown on the Continent in the treatment not only of venous diseases, but of gynaecological conditions, rheumatism, diseases of nutrition, and skin diseases. During the great war a large number of officers and men were successfully treated there for varix, ulcers, and the after-effects of phlebitis. Dr. Boyce has had personal experience of the efficacy of the waters in the treatment of phlebitis. He recently completed a cure for recurrent attacks of phlebitis in the leg; as a result he has abandoned the use of stocking or bandage and the discoloration and pain have disappeared, although the leg still swells considerably after walking. Bagnoles is best reached via Paris (Gare des Invalides), from which it is five hours' journey; there also through carriages during the season (mid-May to end of September).

FETID EXPECTORATION.

FROM time to time correspondents write to call the attention of the profession to the value of garlic in bronchitis, especially when accompanied by fetid expectoration. Recently we have had a note from Dr. Vallabhdas N. Melita, L.M. and S. (Virangam, Bombay Presidency), who states that in a case in which there was a slight elevation of temperature and the expectoration was horribly fetid, he gave injections of garlic oil daily for twelve days. A great improvement ensued, and the fever completely disappeared. The patient was advised to include garlic in his diet for the future. The dose used is not stated.

ALUMINIUM COOKING VESSELS.

IN reply to a correspondent, we stated on August 19th, p. 332, that aluminium is the best metal next to gold or platinum for culinary utensils, and was better than silver. The reference to gold and platinum seems to have caused some amusement, but in answering a chemical inquiry it seemed better to give the exact facts. Dr. Gower Gardner (Oxford) now asks about the action of alkalis on aluminium, as he has heard that an alkali such as washing soda quickly "corrodes" aluminium. He also states that an objection to aluminium is its liability to turn black when used for boiling milk.

*. It is true that aluminium suffers corrosion in the presence of alkalis, and the effect on cabbages and green vegetables cooked in aluminium vessels may therefore have some theoretical interest since it is usual to add sodium carbonate or bicarbonate to the water in which they are boiled. The rate of action on the metal depends on the alkalinity of the liquid; with caustic alkalis it is rapid; with carbonates much less rapid, and with diminishing concentration of the alkali it is further retarded; at the dilution in which alkaline taste ceases to be apparent there is no perceptible effect. Under ordinary conditions small traces of aluminium will pass into solution in the form of aluminium hydroxide and this will be taken with the food *pari passu* with the soda, in quantity approximating to, at most, a few hundredths of the amount of soda. In other words, the total effect would be equivalent to increasing by about double, the proportion of aluminium hydroxide already existing from natural sources in the water in which the vegetables are cooked. The statement that aluminium vessels are liable to turn black when used for boiling milk would appear to be founded on exceptional experience. No other report of this effect has been heard of in the course of our inquiries. The following is, however, a possible explanation: if any film of a spongy nature, such as oxidized metal or milk protein from a previous boiling, is left on the inner surface of the vessel, a new addition of milk being absorbed by the film would be subjected to superheating; the scorched within the film would produce a black stain.

HERPES WITH FACIAL PARALYSIS.

DR. J. F. GORDON (Maghull, Liverpool) submits brief notes of the following case as a possible basis for discussion: About a week ago (he writes) I was sent for to see a patient, a male aged 72, suffering from herpes of the suboccipital and facial regions. The case was a typical one, eruption very pronounced and profuse, the neural pain intense. I prescribed the treatment usually adopted in such cases: locally powder, covered with gamgee, an anodyne and sedative mixture to combat the pain and insomnia. I saw my patient again on Sunday last. His wife, with whom I had a conversation while he was being sent for (as he had gone out for a walk), informed me that he had two nights' good sleep and was now practically free from pain. She said that in every respect he was right, save that the intensity of the pain during its severity must have twisted his face crooked! On his arrival I at once saw he had typical facial paralysis. I have had many cases of herpes in a long professional experience (several over the areas involved in the present case), but never one with facial paralysis coincident with the eruption. Regarding as one does the neuritis (which almost invariably accompanies a case of shingles), as also the eruption (which is coincident with or follows soon after the neural pain), as usual conditions which are looked for, and admitting that a neuritis may be followed by paralysis over the area affected, is this coincident occurrence of the eruption and facial paralysis not somewhat unusual?

THE PERUVIAN ANDES.

SEÑOR OSCAR VÍCTOR SALOMÓN, Consul-General for Peru, writes to us objecting to a sentence in the brief report (JOURNAL, June 17th, 1922, p. 956) of a lecture delivered by Mr. Joseph Barcroft, F.R.S., at the Royal Institution, on the physiological effects at high altitudes observed during the recent expedition to Peru. Speaking of some customs of the inhabitants of the Andes, Mr. Barcroft is reported to have said:

"When a native was very ill, for instance, the date of his funeral was fixed without reference to his convenience, and an official saw to it that he was ready to keep the appointment!"

Señor Salomón expresses surprise at this repetition of this piece of hearsay by an eminent man of science, and suggests that the story might have been "the authorities of the Peruvian Government" a tribute to the exhilarating climate of the Sierra slopes; our correspondent concludes:

"I am in a position, in all matters relating to the Cordilleras of Peru, to speak from the vantage point of six years of travel through their entire length and breadth, and not, as in Professor Barcroft's case, from a mere two weeks' sojourn among vast mountain chains which, together with their debilities, demand long acquaintance before the traveller can speak with the infallible voice of fact."

Señor Salomón acknowledges that his letter is based on an extract from our report published elsewhere. The sentence, as printed by us, ended with a note of exclamation, suggesting that the lecturer did not mean his anecdote to be taken too seriously.

A BY-PRODUCT OF THE JAMAICA HOOKWORM CAMPAIGN.

AN official gazette is one of the less likely places to find humour, and the following letter, printed in the report of the Jamaica Hookworm Commission in the *Jamaica Gazette* for June 22nd, 1922, deserves wider publicity:

"Dear Doctor, I James Tucker who being one of your patient I dear say I congratulate you for your attendance and your good service for I am able to say that I take your treatment four time and since I began to take the treatment I feel Strong and Healthy. Your annual Service had make me Pleasant and Good. Before your treatment all Different had feelings Darkness of eyes Headach goodness and Several Feeling which is not good. But thank God for this Medical Service which the Government give us and I never neglect by taking it. And it dun a good for me. Please doctor Respected Sir, when taking the treatment it comes very simple to me but now I feel quite Amusing to myself and am able to eat and drink very Healthy now all bad feeling is senter away. Dear Doctor I am your Sincere Patient."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 28, 29, 32, 33, and 34 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 30, 31, and 32.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 112.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

185. The Limitations of Intravenous Medication.

THE practice of intravenous medication has come to the front to an ever-increasing extent; and, though by no means a new procedure, its application to the treatment of disease has assumed such proportions that C. VOEGTLIN (*Journ. Amer. Med. Assoc.*, August 5th, 1922, p. 421) regards it as both timely and important to consider the real merits and limitations of this therapeutic method. The intravenous use of salvarsan and its substitutes has done more than any other single factor to popularize intravenous treatment. The demonstration of the relative harmlessness of intravenous salvarsan injections has prompted physicians to apply this method within recent years to other drugs and to other diseases, principally on the assumption that intravenous injection is of necessity followed by a more powerful therapeutic effect than is administration of the drug through other channels. The fact was forgotten that the intravenous administration of salvarsan was simply an attempt to avoid pain and local reaction, and that it was not introduced in order to increase the therapeutic effect. With regard to the efficacy of intravenous quinine injections, clinical observers agree that the action in extreme cases is more prompt than when the drug is given by mouth, and the patient's life may thus be saved. However, as soon as the critical condition has passed quinine should be given by mouth for the reason that the available evidence shows that malaria is not more readily cured by intravenous medication; and this is supported by some recent findings which indicate that about 90 per cent. of the quinine injected intravenously in man disappears from the blood within one minute, and is stored in the tissues. Voegtlin states that what has been said concerning the superior value of intravenous medication with regard to the therapeutic effect is sufficient to raise a question as to the unscientific claims made by certain commercial interests who advertise a great variety of drugs put up in solution for intravenous use. Many of these products are sold under misleading claims regarding their alleged safety and efficiency. It appears that a considerable amount of evidence has accumulated in recent years which indicates that the nicely adjusted equilibria of the blood and those of the easily accessible tissues may be temporarily upset by intravenous medication; and this disturbance may give rise to undesirable symptoms and even cause death. In many cases untoward reactions can be avoided by introducing the drug solution at a slow rate, which permits the protective mechanism of the blood and tissues to operate efficiently; whereas, if the injection rate is too fast, this mechanism breaks down, and symptoms make their appearance as visible results of the disturbance of the chemical or physical equilibrium of the blood and tissues. Voegtlin suggests that we should strive to simplify the technique of the administration of drugs wherever possible, in order to avoid the necessity of the injection of the medication directly into the circulation. The subcutaneous injection of morphine and similar drugs is an exceedingly simple procedure, which very often is left to the attending nurse. Would it not be a great step forward if such drugs as salvarsan or its substitutes could be given subcutaneously? The author urges that every effort should be made to render the administration of such drugs as simple and safe as possible, without, however, sacrificing their therapeutic efficiency. Intravenous medication will, he believes, never serve this purpose, and will always have a more or less restricted field of usefulness.

185. Syphilis and Mental Deficiency.

KEY and PIJPER (*South African Med. Record*, April 22nd, 1922, p. 142) report the results of their investigations into the part played by syphilis in the causation of mental deficiency in 217 cases. The diagnosis of syphilis was based solely upon the Wassermann reaction, and, although looked for in each case, the stigmata of hereditary syphilis were very seldom present. The degree of mental deficiency was based upon intelligence tests, the Stanford revision of the Binet-Simon scale being used, giving the mental age of an adult idiot as under 3, of an adult imbecile as between 3 and 7, and of an adult feeble-minded as between 7 and 11 years, borderline cases being excluded. The highest degree of positive Wassermann results occurred in the lowest degree of amentia—namely, idiocy—and of the 217 serums examined 120 (55.2 per cent.) were positive. To a certain extent the incidence of the test decreases as age advances, and the same applies to its intensity after the age of 25. There does not appear to be any symptom, or group of symptoms, common to those giving

a positive reaction, and it is doubtful if the syphilitic virus is the sole agent responsible for the amentia in all the cases, some other predisposing cause probably being present in most of them, syphilis, though a sufficient factor in itself, often exerting a deciding influence where morbid heredity or other unfavourable conditions are present. Could the family histories have been thoroughly investigated it is highly probable that a fairly large proportion of them would have shown a neuropathic inheritance, and, if ever such investigations can be systematically undertaken, the institution of antisyphilitic treatment in parents, and their children from birth, would exercise a decided check upon the growth of the mentally deficient population in South Africa.

186. Aspirin in Asthma.

V. RUBOW (*Ugeskrift for Læger*, May 25th, 1922, p. 586) has found that in many cases aspirin is most effective in preventing attacks of asthma at night. But in four out of 70 cases aspirin precipitated violent attacks of asthma, probably on account of idiosyncrasy to the drug. A somewhat similar effect is sometimes obtained with atropine, and in the case of aspirin, which tends to dry up the mucous membrane in cases of protracted or acute rhinitis, it may be that its action on asthma depends on its reduction of the bronchial secretion. In the exceptional cases in which aspirin provokes asthma instead of aborting it the explanation may be that, by drying up the secretions too effectively, the patient is unable to clear the bronchial tubes of fluid already secreted. S. BANG (*Ibid.*) also stresses the duplicity of the action of aspirin in asthma. Sometimes the drug has an almost specific curative effect, and even when the disease has lasted for years and has become severe a rapid and complete cure may be effected by the consistent exhibition of aspirin. One of his patients was a man treated in hospital for asthma and emphysema. For several weeks he had suffered from numerous and severe attacks every day. Immediately after the administration of 1 gram of aspirin he was seized with an attack of unprecedented severity, with collapse, great cyanosis, and tachycardia. He rallied after stimulants were given, and for the next two weeks he was almost free from attacks. Then, without his knowledge, he was given 5 cg. of aspirin. Half an hour later a severe attack, with dyspnoea and cyanosis, set in. J. BUCHHOLTZ (*Ibid.*) notes that phenacetin, as well as aspirin, may be very dangerous in asthma, and he records a case in which the administration of 1 gram of phenacetin was followed in a couple of hours by most severe asthma and complete cessation of respiration. Artificial respiration had to be continued for about an hour.

187. Herpes and Facial Paralysis.

G. WORMS and V. DE LAVERGNE (*Paris Médical*, June 10th, 1922, p. 431) consider that the researches of numerous French, American, and Belgian observers have proved that herpes zoster is due to an infective agent, which, when it attacks the geniculate ganglion, produces facial paralysis at the same time that a circumscribed vesicular cutaneo-mucous eruption appears in certain definite regions. They are of opinion that as the Gasserian ganglion is homologous to the posterior root ganglion of a spinal nerve, so the geniculate ganglion is that of the sensory branch of the facial nerve (nerve of Wrisberg). They describe the distribution of the sensory branch (1) (through the chorda tympani) to the anterior two-thirds of the tongue; (2) to the internal and middle ear (petrosal nerves); (3) to a portion of the tonsillar region; and (4) to the tympanic membrane, the external auditory meatus, and portions of the concha. They state that when the infective agent attacks the geniculate ganglion pain is felt in all these regions, followed by the appearance of small vesicles in the external meatus, the inner portion of the concha, anterior two-thirds of the tongue, and the tonsillar region; this eruption may be associated with deafness, tinnitus, and vertigo, sometimes with an attack of auditory (Ménière's) vertigo, and finally with total or partial facial paralysis. Souques has termed this association of symptoms "syndrome géniculé"; the authors prefer to add "complet"; they consider that the facial paralysis is due to the compression of the motor fibres by the swelling of the ganglion in the bony canal. They give details of four cases of the disease in young soldiers and of one in a boy of 15. While they are not prepared to say that all cases of facial paralysis diagnosed as "a frigore" are due to this cause, they consider that herpetic infection is the origin of a certain number of cases, and that these may be recognized by the appearance of vesicles on the walls of the external meatus and on the tongue and fauces; these will

disappear quickly or will ulcerate owing to a secondary infection; and they advise a minute examination of these regions, as the pain and fever may seem to indicate an acute otitis media complicated by facial paralysis. In the absence of definite herpetic vesicles in the regions indicated the differential diagnosis may be made after lumbar puncture and examination of the cerebro-spinal fluid, as Brissaud and Sicard have shown that, in the course of herpes zoster, the cerebro-spinal fluid often shows lymphocytosis, with an increased amount of albumin and of sugar.

188. **The Treatment of Tabes Dorsalis.**
R. HENNEBERG (*Klinische Wochenschrift*, July 8th, 1922, p. 1415) gives a careful critical review of the present treatment of tabes dorsalis. It cannot be well condensed into a brief abstract, but several of his conclusions are of practical importance. The syphilitic origin of tabes can no longer be doubted, but it cannot be cured. The spirochaetes produce their injurious effects on the posterior nerve roots. By neuritic and perineuritic changes (at Nagelotte's points) the nutrition of the root fibres is affected. The results of the syphilitic inflammatory processes at these points are cicatricial connective tissue changes, which can no longer be influenced by any antisyphilitic treatment and are as injurious as the syphilitic inflammation itself. Hence the unsatisfactory results of antisyphilitic treatment. But many consider that mercurial treatment is of service in early tabes and is indicated especially as an introduction to salvarsan treatment. Mercurial liniments may be employed, or injections of mercurial or arsenical and mercurial preparations (embarlin or novasurol). The old salvarsan failed; intradural injections of salvarsan are not to be recommended. The author agrees with those who consider that a repeated mild combined mercury and salvarsan treatment is indicated. He has treated a large number of cases of early tabes with neo-salvarsan and embarlin, or mercurial liniments. In no case had the disease a definite progressive unfavourable course, and improvement occurred not infrequently as regards certain symptoms. For the pains of tabes combinations of narcotics and antineuralgic drugs are often of service, such as pyramidon 0.3 gram and veronal 0.3 gram, or phenacetin 0.5 gram and luminal 0.1 gram. Most patients find by experience one drug which is of most service for the relief of pains, and often that drug is aspirin, in rather large doses. The compensatory exercise treatment is of undoubted service. For the perforating ulcers, besides hot-water treatment and hot-air treatment, recently x-ray treatment has been recommended. Overstrain (especially affecting the legs) should be avoided. Syphilitic patients cannot be prevented with certainty from developing tabes, even by careful antisyphilitic treatment. Tabes and general paralysis can only be prevented with certainty by the prevention of syphilis.

SURGERY.

189. **The Urethroscope in the Treatment of Gonorrhoea.**
C. BROWN (*Edin. Med. Journ.*, August, 1922, p. 49) considers that urethroscopic examination is essential in the diagnosis and treatment of gonorrhoea, relapse cases being prevented by the discovery and cure of their underlying cause. In the majority of cases anterior urethroscopy is all that is required, no necessity for examining the posterior urethra only occasionally arising, as in a case of recurrent epididymitis. By affording accuracy in diagnosis the appropriate treatment and its extent are indicated, and the relative values of various forms of therapy can be gauged. Urethroscopy is indicated in chronic urethritis and should not be undertaken until all acute manifestations have subsided. Prior to examination, a multiple glass test of the urine should be made and the instrument should not be used until the urine is clear, though a few "threads" in the first glass only are not contraindications. Other contraindications are a history of frequent acute relapses, active or subacute complications, and anatomical defects, such as a small meatus, for which bougie dilatation or meatotomy may be required. Force must be avoided, the instrument being allowed to glide down the urethra by its own weight, care being taken to prevent its collar injuring the mucosa. Only sufficient light should be used satisfactorily to illuminate the field, since too powerful a light dazzles. The lustre of the mucosa, the condition of the follicles and lacunae, the presence of infiltrates or new growths, and the degree of elasticity of the walls, as tested by air distension, are among the points to be noted. The procedure should be painless and local anaesthesia unnecessary, but in posterior urethroscopy a little novocain should be instilled into the deep urethra beforehand, and after drawing the instrument to glide down to the bulb its beak is

supported against the pubic arch, assisted by a finger in the rectum, and the cypicope carried downwards until the beak rotates under the pubic arch, when the bladder is entered by sliding the instrument, with the guidance of the finger in the rectum, to the neck of the bladder, after which it is slightly withdrawn. Descriptions of the normal and pathological appearances of acute, subacute, and chronic lesions as seen with the urethroscope are given, together with notes of illustrative cases. The treatment of strictures consists in dilatation with bougies until it is possible to introduce Kollmann's dilator, by which means the stricture can be overdilated until it ceases to recur, thus often effecting a permanent cure when treatment by bougies alone fails.

190. **Traumatic Epilepsy.**
DELLA TORRE (*Archiv. Ital. di Chirurg.*, May, 1922, p. 349) publishes nine cases of traumatic epilepsy induced by head injuries in the war. In all the cases the onset of the epilepsy was very early. Full details and comments are given for each case. The nine cases were part of the first hundred cases of head injury seen during 1915 and 1916. In six the epilepsy was of the Jacksonian type, and in three generalized. There was no hereditary history of epilepsy in the cases, and none of them had an epileptic fit at the time of the injury. Rapid loss of consciousness was a marked feature of the attacks. Free craniectomy and preservation as far as possible of the meninges were practised. The subsequent history showed that seven were cured absolutely, whilst in two the fits reappeared in two and six months after operation. Of the cured cases one suffered from persistent weakness of the left leg, and another from continual buzzing in the ears.

191. **Accidental Wounds of the Bile Ducts.**
M. SAVARIAUD (*Bull. et Mém. Soc. Chir. de Paris*, June 20th, 1922, p. 864) reminds us that accidental wounds of the bile ducts in the course of cholecystectomy are far from being rare. He records two cases where the operative procedure was straightforward, without haemorrhage or difficulty. In the first case, on pulling on the gall bladder, the hepatic duct was drawn up and a portion was cut out of the side wall of this duct. In cases of retrograde cholecystectomy wounds of the common bile duct are due to the shortness of the cystic duct, the surgeon mistaking the cystic for the common duct. The chief cause of these injuries is the difficulty of recognizing the junction of these three ducts; this is greater in the presence of adhesions or when a stone lies at the termination of the cystic duct. The best means of avoiding accidental injury of the ducts is by returning to the old method of gradually dividing with scissors from the fundus of the gall bladder to the junction where one can see the opening into the common duct. When the surgeon perceives his mistake he should be able to repair it forthwith. In case of a lateral loss of substance he has the choice between suture or healing by second intention over a tube; in case of complete division either end-to-end suture or implantation to the stomach or duodenum. In cases where a fistula has formed the upper end of the duct should be implanted into the stomach or duodenum; searching for the lower end is useless and open to the dangers of haemorrhage or wounds of the duodenum. End-to-end suture is more difficult than implantation into the intestine, and is liable to end in cicatricial stenosis.

192. **Surgery of Toxic Goitre.**
C. F. NASSAU (*Therapeutic Gazette*, May 15th, 1922, p. 305) points out that surgical mortality is unusually high in cases operated upon in a state of progressive hyperthyroidism, and that in such cases palliative measures should be adopted rather than the radical operation. X-ray treatment is of greatest value in adolescent thyroid enlargement, but is useless in cases of colloid or adenomatous goitre. The type of operation depends upon the patient and the stage of the disease, and in very grave cases multiple steps may be necessary by ligation of one vessel, to be followed later by ligation of the second vessel, and then partial, and finally complete, lobectomy. During acute thyroid crises operation must be avoided, the patient being treated by rest, fluids, and careful nursing until weight is gained, with a corresponding subsidence of pulse rate, nervousness, and irritability. Ligation has for its object the testing of the patient's suitability for, or as preparatory to, thyroidectomy, a week usually intervening between ligations. Although the improvement after ligation is often so striking as to give the patient the impression of being cured, lobectomy should always be urged about three months later to minimize the possibility of relapse. In mild cases a wedge-shaped bilateral resection, with complete suture of the capsule, will usually suffice, but in the severe cases only a thin layer of thyroid tissue lining the posterior surface of the capsule should be left, one-sixth of the gland being sufficient to maintain normal function.

538 a

adium application. Five patients, aged from 15 to 18, in whom myopathic haemorrhage had resisted all other therapeutic measures, were given three to eight hours' exposures to 25 mg. of radium element; temporary amenorrhoea followed, but menstruation was re-established in all cases within fourteen months, and in four instances was normal.

196. Atypical Menopausal Phenomena following X-ray Castration.

ACCORDING to E. VOGT (*Zentralbl. f. Gynäk.*, June 4th, 1922, p. 914), excessive haemorrhage is a rare accompaniment of the artificial menopause following x-ray castration, and occurred in only 10 cases among 1,300 observed by him. In 8 instances an anatomical cause of the bleeding was demonstrated after hysterectomy—in 3 cases myoma (two being submucous), in 3 adenocarcinoma of the uterus, in 1 pyometra, and in 1 an antecedent hydatidiform mole. The haemorrhage occurred from one-half to five years after the radiation, and the patients were aged from 40 to 58. The adenocarcinoma developed five years in two cases, and six months in one case, after radiation. Although it is not possible with certainty to ascribe the onset of any of the complications recorded to the influence of x-ray treatment, these cases show that caution should be exercised with regard to the prognosis given to the patient before treatment; they point also to one of the disadvantages of x rays as compared with operative treatment of excessive uterine haemorrhage.

197. Treatment of Occlusion of the Fallopian Tube.

ACCORDING to W. T. KENNEDY (*Amer. Journ. of Obstet. and Gyn.*, June, 1922, p. 667), insulation of the Fallopian tubes with carbon dioxide, as described by Rubin, leads in some instances to the detection of tubal obstructions which produced sterility. Such a diagnosis being established, and evidence of acute or subacute salpingitis being absent, the writer opens the abdomen, separates adhesions in the neighbourhood of the fimbriae, and uses the following procedures for restoring and preserving tubal patency. A bristle-ended solid silver probe is passed along one tube, from the outer extremity, into the uterine cavity; it is subsequently replaced by a hollow silver probe of 0.75 to 1 mm. diameter. The other oviduct is similarly treated, and if there are signs of old inflammation the tubes are irrigated with alcohol by attaching a syringe to the outer end of the hollow probe. Resection of a part of the tube or tubes, if necessary, is done at this stage. The hollow probe is now made to traverse one Fallopian tube, then the uterine cavity, and then the other tube; the cut ends are anastomosed. To a strand of piano wire which has been passed through the hollow probe is affixed a strip of Cargile membrane 40 cm. long and 3 cm. wide. The probe and wire having been withdrawn, the membrane is left traversing both tubes and the uterine cavity. About 7 cm. of membrane protrudes from the fimbriated extremity of the tube on each side; the outer end of the membrane is sutured to the broad ligament as a precaution in case pregnancy should occur before the membrane is absorbed.

PATHOLOGY.

198. The Precipitin Test of the Arachnoid Fluid.

IN many abnormal conditions of the central nervous system there is an increase in the protein content of the cerebrospinal fluid. In order to detect this and to form some quantitative estimate as to its amount, C. A. NEYMANN and L. HEKTOEN (*Journ. Nerv. and Mental Dis.*, July, 1922, p. 16) have had the happy idea of preparing precipitating serums to various kinds of protein and testing their effects on the arachnoid fluid of the patient in question. In some cases the serums were obtained against pure solutions of albumin or of globulin, and in others by using the cerebrospinal fluid of a parietic as the antigen. The test, which is carried out by the usual ring technique, is very simple, and can be performed with not more than a few drops of the arachnoid fluid. The results appear to agree very well with the other tests, such as the Wassermann, Pandey, and colloidal gold, used for the detection of cerebral disease. Actually, they find that in general paralysis of the insane the fluids react in dilutions from two to eight times those of the normal maximum, and that this reaction is far more strongly marked with anti-globulin than with anti-albumin serum. In tabes the increase of the globulin fraction is not so well marked. With epilepsy the tests show the presence of a greater amount of albumin than normal. Slight reactions are obtained with fluids from patients suffering from dementia praecox or epidemic poliomyelitis. It seems possible that if, after the collection of data by several observers, the results are as favourable as those obtained hitherto, the test may, by its very simplicity, come to be regarded as a most valuable one.

199. The Leucocytes in the Capillary and Venous Blood in Scarlet Fever.

T. MIRONESCO and A. CODREANU (*Bull. et Mém. Soc. Méd. de l'Hôp. de Paris*, May 11th, 1922, p. 752), as the result of examination of nine cases of scarlet fever and five of other diseases have found that with one exception in all the cases of scarlet fever there was a larger proportion of the leucocytes in the capillaries of the skin than in the veins of the elbow during the eruptive period. Thus in one case there were 28,600 leucocytes in the capillaries and 18,200 in the elbow vein. In the other diseases examined this relation between the capillary and venous leucocytes did not hold good. Thus in a case of pelvic peritonitis there were 34,000 leucocytes found in the capillary blood as compared with 40,200 in the vein, and in a case of typhoid fever there were 4,000 leucocytes in the capillary blood and 4,200 in the venous blood. The writers believe that the pathogenic agent of scarlet fever is abundant in the skin, and that the leucocytes favoured by vasodilatation convey the defences of the organism to the periphery. They are therefore found in greater numbers in the capillaries than in the venous blood.

200. Vitamins for Yeasts and Bacteria.

L. FREEDMAN and C. FUNK (*Journ. of Metabolic Research*, April, 1922, p. 457) have studied the nutritional factors in the growth of yeasts and bacteria, with special reference to the necessity of substances known to contain vitamin B. They find that certain substances are present in beef and ox-heart infusions, in peptone and autolysed brewers' yeast, which show a strong growth-stimulating activity on both haemolytic streptococci and yeast cells. By shaking with certain adsorbents, such as fuller's earth and charcoal, they were able to extract these active substances from their natural sources, and to recover them from the adsorbent by baryta and acetic acid. They find the active substance to be similar to the so-called vitamin D, and observe also that another substance is present in beef and ox-heart infusions which is necessary for the growth of haemolytic bacteria, a substance probably associated with haemoglobin. In studying the effects of various proteins in bacterial growth they found that certain substances can be obtained from purified casein, commercial gelatin, yeast protein and edestin, which show marked growth-stimulating activity on haemolytic streptococci. Hydrolysates of purified egg globulin, lactalbumin, and hordein only contain traces of this stimulating substance, whereas other proteins examined failed to show its presence. These active substances are not a constituent part of the protein molecule, but the amount present depends on the physical and adsorptive properties of the protein and on the method and degree of purification. These substances also are probably related to the water-soluble vitamins obtained from brewers' yeast, particularly the so-called vitamin D.

201. Bacteriology of the Mouth.

A. L. BLOOMFIELD (*Johns Hopkins Hospital Bull.*, July, 1922, p. 252), in attempting to answer the question why it is that the "normal" flora of the mouth continue to flourish in the buccal secretions, whereas other organisms are rapidly eliminated, has carried out a series of experiments with the object of removing the bacterial flora of the tongue by thorough washing with water, scrubbing, and copious irrigation. Such mechanical cleansing carried out for thirty minutes failed to remove the normal bacterial inhabitants of the tongue, showing that such organisms are not growing free in the mouth secretions but are intimately bound to the mucous membrane, just as are foreign organisms in a focus of infection. The organisms could not be drawn out from the deeper cells of the mucous membrane by the application of strongly hypertonic solutions and the salt pack. The actual niduses of growth of the bacteria must therefore be in the crevices of the epithelium and in the gland orifices; here they multiply, certain organisms being thrown off and removed just as are foreign particles or bacteria experimentally introduced. Confirmation of this hypothesis was derived from the results obtained from the introduction of extraneous organisms into the mouth, it being shown that such abnormal inhabitants are to a large extent eliminated by the mechanical lavage which failed to remove the normal flora. Thus any organism which persists on a normal mucous membrane for more than a few hours must be in vital biological relationship to the mucous surface, otherwise it would be removed as a foreign particle by the normal eliminative mechanism. The saliva, as a rule, plays no significant part either favourable or inhibitory. For this reason bacteria, such as the colon bacilli, which thrive in saliva *in vitro*, are not found in the normal mouth, whereas organisms such as pneumococci or influenza bacilli, which die in saliva *in vitro*, are frequently present.

Observations

ON

OSTEO-ARTHRITIS OF THE HIP.*

BY

GEORGE PARKER, M.A., M.D.,

HONORARY CONSULTING PHYSICIAN TO THE GENERAL HOSPITAL, BRISTOL.

OSTEO-ARTHRITIS of the hip, though common, is so often overlooked or mistaken for sciatica or subacute rheumatism that it seems worth while considering its symptoms in detail, especially since its progress and successful treatment largely depend on its early recognition. I ask attention first to a tabular classification of joint diseases, so that I may make quite clear what type of disorder it really is. The confusion of names in chronic joint diseases is so great that even a tentative classification may be of use.

GROUP A.

- Traumatic arthritis.
- Haemophilic arthritis.
- Tubercle and syngo-myelic arthritis.
- True gout.
- Heberden's nodes.
- Acromegalic joints.
- Pulmonary osteo-arthritis.
- Spondylitis, Type A.
- Osteo-arthritis multiplex.
- Osteo-arthritis of the hip.

GROUP B1.

- Purulent arthritis—for example, streptococcal or pneumococcal joints.
- Arthritis due to typhoid and other fevers, to dysentery, diphtheria, etc.
- Syphilitic arthritis.
- Tuberculous arthritis.

GROUP B2.

other chronic infectious forms.

GROUP B3.

True rheumatism, acute and subacute, and fibrositis.

In the diseases in Group A we find some features common to all; for example, little or no affection of the fibrous or synovial structures beyond effusion, but great changes in the cartilago and bone, for both of them may show irregular destruction and abnormal overgrowths—that is, not adapted to the functions of the joints. The cause of most of these diseases is disputed, and as a rule there is no fibrous or bony ankylosis.

In Groups B1, B2, and B3 we find septic causes generally acknowledged. The chief incidence is on the fibrous and synovial tissues. In some the condition goes on to suppuration and its results, or the formation of specialized formations. In others it never does, but (in B2) to atrophy of all structures with fibrous overgrowth and ankylosis. In the third (B3) subdivision there are no permanent joint changes, but the tendency to fibrous affections outside the joints interferes for some time with perfect movement. Flat-foot and stiff joints may last for months, but the distinction due to the absence of permanent changes seems to me an absolute one. Again, in all of these diseases pyrexia and other so-called constitutional results of the septicaemia are prominent, but in none do we find hypertrophy or outgrowth of bone.

I must not discuss the endless names which have been lavished upon the affections in B2, such as rheumatic gout, arthritis deformans, etc., but would emphasize their septic, non-suppurative character. Spondylitis has been shown to be of different types, some belonging to Group A and others to B. I have seen specimens in the bones of the cave bear of the Mendips, and Elliot Smith found whole cemeteries of prehistoric men so affected that the wonder is how they could bury each other, and the population in the same sites is ravaged by the disease to-day. It is, perhaps, the most ancient disease known. It is so common in draught horses now that many of them can never lie down, and a broken back in them is often merely a fracture of the common lumbar ankylosis or ossified ligaments. I cannot learn that these animals ever suffer from hip-joint disease, though osteo-arthritis of the distal bones is common enough.

Cases of osteo-arthritis of the human hip form a clinical and perhaps a pathological group with a distinct character,

but this is true only if we exclude hip affections due to Charcot's disease, real gout, and the various infectious diseases of Group B2 with their constitutional symptoms such as fever. In this last type other joints are nearly always involved, though occasionally we find a gonococcal hip alone in its suffering; even true rheumatism may leave some hip trouble for a time, but this finally clears up, and is not usually difficult to diagnose if the history is considered carefully.

Adams in 1857, in his treatise on *Rheumatic Gout or Chronic Rheumatic Arthritis*, divided osteo-arthritis into *local* and *general*. Jones Llewellyn thinks it asymmetrical, and usually confined to large joints. Adams gave to the hip-joint type the name of "morbus coxae senilis" as early as 1837, but afterwards found so many cases of it at 30 or 40 years of age that he tried to blot out the name. I have recently seen some twenty cases in patients varying from 29 to 70 years of age, and have been struck with the way in which they get labelled sciatica; with the little pain usually complained of, which is so unlike the classical accounts of morbus coxae senilis, where the pain is described as persistent and violent; and above all with the perfect good health of most of them. They may complain that they cannot lace their boots or put on their stockings, and that they have stiffness or limited movement in one or both hips with a feeling of fatigue or pain in the morning and after prolonged exertion. The disability may increase until little or no movement takes place in the joint, and if both hips are thus affected they can hardly separate their feet or move one foot in front of the other. Their helplessness and imprisonment becomes very serious and depressing and the outlook most gloomy.

Sometimes the limb presents an exact picture of an impacted fracture of the neck of the femur with rotation outwards and apparent or real shortening. This was the case with Matthews the comedian, who was thrown from his gig and lamed. Ten years later he died and his bones were shown at a medical meeting by Adams, who demonstrated that the supposed fracture was merely this disease.

Compared with these monarticular cases, the instances of rheumatoid arthritis, where the hip is only one of the joints affected, are far more numerous, and the prognosis of the hip seems to be actually better. For the tendency in rheumatoid arthritis is to pass after years of suffering into a state of quietude with deformed and ankylosed joints. Now the hip being less disorganized than the small joints will sometimes recover surprisingly when the septic fire has burnt out.

I must confess that some authors think that osteo-arthritis of the hip may follow similar changes in other joints, or that an extension to other joints may follow it. Jones Llewellyn goes farther, and quotes Preiser as saying that fourteen cases of this hip affection have been found in children in Germany. However, I have never seen it in children, and I doubt whether it ever extends to other joints.

Symptoms.

I will now consider the symptoms commonly encountered.

1. There is stiffness at the joint. The patient sits down with difficulty and cannot as a rule cross the affected limb over the other or lace his boots easily. There is a sense of fatigue which, with the stiffness, passes off under gentle exercise, but the patients are healthy and well nourished.

2. Pain is absent at first, and when it begins it is deep-seated in the groin and behind the trochanter, and it may become severe. Referred pains along the neighbouring nerves are common and important. More frequently they run down to the knee and along the outer side of the thigh. Meralgia paraesthetica of the external cutaneous may appear. J. Llewellyn remarks, "Simultaneous pains in the anterior crural, obturator, and sciatic are very indicative of this disease," and "lumbar pain from strain of the ligaments is often secondary but not prior to the hip trouble, which is the reverse of what is found in sciatica."

3. Tenderness of the capsule in the groin and at the back of the limb is common.

4. Pseudo-locking may happen at times. Here a sudden pain with a feeling of something in the joint may come on, followed by lameness for some hours. This has been variously attributed to synovial nipping or to subchondral foci of inflammation.

5. Attitude.—The patient by choice stands on the sound limb, and rests the toe of the affected limb on the ground with bent knee and eversion of the leg—external rotation. The pelvis is drawn up and the lumbar column is curved.

* A paper read before the Bath and Bristol Branch of the British Medical Association.

convexity towards the diseased side. The patient walks with a limp, moving the foot forward with difficulty.

6. *Tonic Flexion at the Hip.*—When the patient lies supine on a table there is lordosis and an arched buttock. If the knee is pressed down the lordosis is increased. This is an important test.

7. *Passive movements are limited*, even at an early stage. Thus extension, flexion, internal rotation, and abduction are hindered or impossible.

8. There is *shortening*, though less than it seems, and in later stages this may increase from absorption of the neck of the femur.

9. *Wasting of the gluteal muscles*, which does not occur in sciatica, and also of the thigh, may be present.

10. In later stages *loud grating in the joint* is heard and felt, and *exostoses and obliteration of the outline of the joint* are seen in skiagrams.

It is important to remember that the stiffness of gait and limitation of movements may be present long before any evidence of bony change is shown in skiagrams or otherwise. We may call these two stages the functional and the organic ones.

Pathology.

In fully developed cases the cartilage becomes roughened and softened, fibrillated and thinned, especially at the centre, while at the periphery it is thickened. Nodules of overgrowth appear and become calcified. Where the cartilage has nearly disappeared a layer of ivory-like bone takes its place, and this is often grooved by friction. This process is quite unlike that seen in chronic infectious arthritis, where "ulceration," perforation, and fibrous ingrowths appear.

Below the cartilage atrophy and absorption of bone takes place. The trabeculae are changed into fibrous tissue, and even the marrow, but new bony outgrowths are formed in places. Thus simultaneous absorption and production of bone goes on. As R. Stockman says, the process does not resemble any known inflammatory condition. He adds that it is hard to say whether the changes commence first in the cartilage or in the bone. Absorption of the neck of the femur may follow, and either rarefaction or condensation of the shaft. At a late stage the synovial membrane degenerates, but it is doubtful whether there is at first any hypertrophy.

The Causal History.

Jones Llewellyn points out that the disease often follows a strain or blow on the great trochanter, and still more often supervenes on a state of flat-foot, genu valgum, or an inequality of length in the two limbs. Any of these causes, he says, may prevent the joint surfaces from corresponding, the capsules and ligaments are strained, the synovial fringes hypertrophy and multiply. The synovial arteries show thickened walls and often an obliterated lumen. Mr. T. S. P. Strangeways, of the Research Hospital, Cambridge, in a private letter, tells me that this form of osteo-arthritis is more commonly seen in better-class patients. He would prefer the name of "arterio-sclerotic joints," and considers that the condition is associated with overwork, that a large proportion of his cases have been athletes, and are men who have ridden on horseshack a great deal. The changes he finds on microscopic examination are fibrosis of the capsule and distinct thickening of the vessel walls. He considers that these changes may bring about changes in the nutritive value of the synovial fluid, which, he holds, in normal circumstances, is a source of nourishment for articular cartilage (see BRITISH MEDICAL JOURNAL, May 15th, 1920). In his opinion it is the alteration in the nutritive value of the fluid which leads to degeneration, fibrillation, and loss of elasticity of articular cartilage, followed by disintegration and exposure of the bone covered by the affected area. Thus the weight of the body is thrown directly on the bone of the articulation. This causes a thickening and condensation of the exposed area, and if the movements of the joint are maintained, polishing and eburnation follows.

This connexion with arterio-sclerosis is supported by some few observations. I believe that in some forms of uterine disease a local arterio-sclerotic change is not uncommon. If such a cause is operative we might expect to find osteo-arthritis frequently in the subjects of generalized arterio-sclerosis, but fully developed cases are not very common, though minute patches of degeneration in joints without

clinical symptoms are frequently seen in skiagrams and at operations, the meaning of which is not clear.

There is no evidence of a neural origin of the disease such as is present in a Charcot's joint, and very little in favour of an endocrine source, though osteo-arthritic changes occur in acromegaly, and the closely allied knee disease seen in some menopause patients is often accompanied with myxoedematous changes. Garrod, too, has noted a brawny infiltration of the hands in some instances of multiple osteo-arthritis, of which I have seen cases. There is at first sight little to be said in favour of an infectious origin, but this theory has recently found much support in the researches of P. W. Nathan and others. They claim to have shown that all the extraordinary changes in rheumatoid arthritis are due to the lodgement of streptococci and other organisms in the neighbourhood of joints where the circulation is least active. By the injection of haemolytic streptococci, pneumococci, and staphylococci into animals they assert that they have reproduced most of the joint changes found in man in rheumatoid arthritis (and, they add, in osteo-arthritis), both acute and chronic, inflammatory or degenerative, cases with general constitutional symptoms, or merely transient ones, followed afterwards by progressive joint disease, or by gradual recovery, or by recurring joint attacks. In these cases where the general symptoms are quite transient, the morbid process may be localized at a joint, if there is a focus of infection left near it, quiescent for a time perhaps but capable of fresh action long after the general health is perfect and the original wound or carious tooth has been sterilized. Thus in hip-joint disease they would postulate a transient general infection, an equally short infection of many joints, and a focus of infection left near one hip, which henceforward shows progressive changes, at first inflammatory and then degenerative.

We have, then, to compare two different views—the purely mechanical one of Strangeways from the cutting off of nutrition leading to the degeneration of cartilage and bones, and the irritation of bone by friction, on the one hand; with the infective theory, on the other, of continued inflammation and softening, followed by degeneration, all due to a local focus of septic organisms.

Certainly the large amount of bone destruction and softening spreading to a long distance is in favour of the latter view of a bacterial poison; but we ought, if this is true, to find frequently near the affected joints collections or foci of organisms like the nests of typhoid bacilli in the peritonitis of typhoid, but this we do not do. Moreover, even in the earliest stages the morbid processes in osteo-arthritis and in rheumatoid or chronic infectious arthritis are so utterly different that it is difficult to accept a common cause. In the one there is an insanity or malignancy of growth, in the other an inflammatory poisoning and atrophy, followed by low form of fibrous repair. Both sides agree that organisms are not found in the joints, or indeed in the joints of true rheumatism. After all, interesting as the question is, the practical importance is perhaps small. Here is a joint which, whether or no there was once a primary bacillary infection, has none now, but owing to a strain or overwork has broken down and started on a degenerative course. Out of the many joints once exposed to a supposed infection, this one only has lost the power of resistance, or suffers from deficient nutrition. Could we on either theory prevent this, or can we check the process?

Treatment.

In the first place, we can endeavour to remedy any obesity, flat-foot, or original shortening of the limb which causes a strain. We can limit the amount of exercise or exertion, and when this is done in an early case the hip symptoms often clear up surprisingly. But this is not all. There is an increasing volume of opinion that if only cases can be diagnosed early enough, and at once given complete rest—for instance, by a long splint with a pair of crutches—a pattern on the sound foot, complete cures may be obtained. Absolute immobilization of the joint is to be aimed at, though difficult to obtain even with confinement to bed. In fact, the patients may be treated, like those having tuberculous joints, with absolute rest from the beginning, before the joint becomes deformed and new outgrowths have developed. Hence the great importance of recognizing these cases at first and of avoiding any error, or mistaking them for instances of gout or sciatica.

We are apt to forget that there is not the tendency to kylosis which exists in rheumatoid arthritis and makes immobilization so dangerous in that condition.

If we meet with cases already at an advanced stage or who refuse immobilization we can, besides correcting any deformity, apply a spica bandage or a leathern moulded splint, and then allow gentle exercise with the toes turned inwards. Radiant heat followed by massage is most helpful at all ages, and in advanced cases passive exercises may be added. Very great relief from pain is given by ionization with salicylates and iodides, hot sandbags, andunction of diclyic acid 3ss, menthol gr. x, lanoline 3iv, with paraff. 1ollis to an ounce, and some increase of mobility may follow. Or drugs we should persevere with arsenic or thymus gland with or without the syrup of iodide of iron. Cholelotomy has been advocated by Sampson Handley, Wheeler, and others. It consists in disarticulating the head of the femur, cutting away the outgrowth, and adapting the head of the bone to the socket. Very good results have been obtained and a freely movable joint formed in young patients where bony changes are not active.

In other cases the joint has been excised and the head mortised to the pelvis with great advantage as to freedom from pain but with complete fixation of the joint.

RECURRENCE OF SYMPTOMS AFTER REMOVAL OF GALL STONES FROM THE GALL BLADDER.

BY

R. P. ROWLANDS, M.S., F.R.C.S.,

SURGEON TO GUY'S HOSPITAL.

It is commonly asserted that the results of cholecystostomy are very satisfactory, that symptoms rarely occur after it, and that secondary operations seldom become necessary. My experience, however, is that although this operation is a valuable one, often saving life and giving great relief, symptoms do return after it in a good many cases, and that the demand for secondary operations is far from uncommon. Many patients whose symptoms recur are so very disappointed that they lose faith in operations and prefer to suffer much rather than undergo a further one. During the last six months I have been asked to operate on four patients whose recurrent symptoms had become so intolerable that they abandoned their natural prejudices. I give below brief notes of three of these cases.

Like the appendix, the gall bladder is a vestigial organ which many animals are luckily born without and numerous human beings have lost without detriment. It is admitted to be by far the chief, if not the only, factory of gall stones, whose power for evil is very great. The infection which is the main cause of cholecystitis and the formation of gall stones is known to settle in the wall of the gall bladder and, in many cases, to be incurable by mere drainage. Chronic irritation of the gall bladder sometimes leads to cancer, which is not uncommonly discovered at an early stage on examining the organ after its removal. The hope of cure in these early cases of cancer is very good; one of my patients thus treated over ten years ago is well now.

It is very difficult to find and to be quite certain of removing every gall stone from the gall bladder, and more especially from the tortuous and indurated cystic duct, where a small stone is easily overlooked. Removal of the gall bladder and its duct is the only certain way of getting rid of all stones in these circumstances. This is well shown in Case I. Even if all the stones are removed by cholecystostomy, with or without incision of the cystic duct, stricture of the duct may ensue, causing a mucocoele or empyema of the gall bladder or mucous fistula. Sometimes a biliary fistula or chronic jaundice follows kinking of the common bile duct due to the contraction of the inflamed gall bladder. If the latter contains pus or other infective matter it is much cleaner and often easier to remove it and its duct without opening them, thus avoiding the risk of infection of the wound, with delay of healing and weakness of the abdominal wall with ventral hernia. The persistence or recurrence of cholecystitis is not uncommon after cholecystostomy, with or without the formation of fresh stones. This point is illustrated in Case II. Although there were no stones the symptoms had closely simulated those of cholelithiasis. Secondary infection of the

bile ducts and pancreas may ensue in these circumstances, causing jaundice or acute or chronic pancreatitis. It has been a common but mistaken belief that draining is always safer than excising a diseased gall bladder, but experience proves that, with a proper selection of cases and a good surgeon, the reverse is true. Thus the mortality of 2,493 cases of cholecystectomy performed at the Mayo Clinic between 1907 and 1916 was 1.3 per cent., and that of 2,854 cholecystostomies was 1.5 per cent.

It is clear that, for disease limited to the gall bladder and its duct, cholecystectomy is more radical than cholecystostomy. It is, however, not invariably the easier and safer operation. Much depends, as I have said, on the wise selection of suitable cases and upon the skill and experience of the surgeon. In acute cases, when the patient is very ill, old, or feeble, when the gall bladder is very inflamed, distended, and adherent, when inflammatory oedema makes it difficult to identify the bile ducts, the surgeon—especially if he is not very experienced in this branch of surgery—will be wise to choose cholecystostomy as the safer operation in the circumstances. It will probably save life, and, if care be taken to remove all stones, the ultimate result may be satisfactory. If serious symptoms recur a secondary cholecystectomy can be performed, in a quiet period, under more favourable conditions.

It must not be forgotten, however, that these secondary operations may be very difficult owing to the disturbance and confusion by adhesions of the normal anatomy of the complicated biliary apparatus. It is very clear that the surgery of the bile apparatus, like that of the stomach and duodenum, is not to be lightly undertaken by the amateur or the novice. The interests of the patient, as well as the good name and honour of surgery, demand special skill and experience from the surgeon who undertakes this work, for it is impossible to tell what difficult and unexpected problems may present themselves and have to be promptly solved when the abdomen is opened. These operations, sometimes so easy, may, on the other hand, be among the most difficult and hazardous in surgery. When medical men realize these facts we may hope to see fewer bad results and secondary clearing-up operations, such as cholecystectomy and choledochotomy, for the removal of stones left in the common bile duct, and the repair of fistulae or strictures following injuries of the bile ducts. To avoid the last named, constant vigilance and an accurate knowledge of the anatomy of the bile ducts are required. It is necessary to identify the common bile duct quite clearly before proceeding to remove the gall bladder.

There is more room for doubt about the indications for cholecystectomy when the disease (especially cholelithiasis) has extended into the main bile ducts. It is evident that the gall bladder should not be removed unless it is certain that the common bile duct is patent and likely to remain so. It is also clear that it is too risky to be undertaken when the patient is very ill, old, or feeble, and especially in the presence of jaundice which has lasted long enough to diminish the coagulability of the blood—as shown by a previous estimation of the clotting period—thus adding the possibility of uncontrollable bleeding to the dangers of the operation. No one, again, would suggest the removal of the gall bladder when infective cholangitis exists, for in this grave condition the only justifiable operation is the removal of stones and the drainage of the common bile duct, and even this should, if possible, be deferred to a quiescent period, when the risk is much less. Under favourable conditions, however, when the bile ducts are patent, it is very advantageous to the patient to have the diseased gall bladder removed, and thus to be saved from the probable recurrence of symptoms, with or without a subsequent radical operation.

CASE I.

A. C., aged 53, a powerful, stout man, had had cholecystostomy performed for acute cholecystitis in August, 1921, through a long vertical incision made below the ninth right rib cartilage. The operation was said to have been a difficult one, but it was thought that all the stones had been removed. Recovery was slow, but ultimately the man returned to work. He was readmitted into hospital before Christmas for return of symptoms, but these abated, and he was sent out without further operation. A few days later he was laid up with fever (? influenza, probably cholecystitis). Another attack came on soon after, with violent pain in the right hypochondrium and slight jaundice. The gall bladder could not be felt, but there was general rigidity and dullness in the right hypochondrium. An immediate operation was advised, but the patient would not undergo it until he was promised that every endeavour would be made to make it final and radical.

Operation (January 16th, 1922).—Kocher incision. Very dense adhesions were found between the liver (lower edge) and the

parietes, and much blood-stained bile below and above the right lobe of the liver. The adhesions were separated with great difficulty. The gall bladder was empty and had perforated on its lower surface. Although the foramen of Winslow was defined it was impossible to palpate the common bile duct to decide if there were any stones in it, owing to the great inflammatory oedema of the subperitoneal tissues and of the head of the pancreas. A small stone was felt in the cystic duct, and this was extracted with difficulty, after opening the duct. No more could be felt. The common bile duct was opened and a large olive-headed probe was passed into the duodenum and up into both right and left bile ducts without difficulty and without encountering any stone.

Although the patient was very ill it was felt that he would not remain well unless the gall bladder was removed. This was done with difficulty, owing to adhesions and inflammatory changes about the ducts which made it difficult to define them. When the gall bladder had been removed another small stone was found in the cystic duct. This was a great surprise. The common bile duct was drained and the patient made a good and rapid recovery. He has remained quite well since.

CASE II.

Mrs. H., aged 49. There was a history of repeated attacks of hepatic colic, without jaundice, since 1917. Cholecystectomy was performed elsewhere in November, 1919, and seventy-two stones removed. The patient remained well until February, 1922, when attacks of very severe pain recurred at frequent intervals, each attack lasting from half an hour to three hours. There was no jaundice.

Operation (March 15th, 1922).—Cholecystectomy performed. There were no gall stones, but a greatly enlarged, folded, inflamed, and adherent gall bladder containing mucus and bile. A chronically inflamed appendix was also removed. The patient made a good recovery.

CASE III.

Mrs. K., aged 64, had had cholecystectomy performed elsewhere in 1914. In 1916 the attacks of biliary colic recurred, and during the next six years she had six severe and many minor attacks. They were attended by nausea, vomiting, and flatulent distension.

Operation (May 25th, 1922).—Cholecystectomy performed. The gall bladder was found to be full of stones, and several were also removed from the common bile duct. The patient did very well.

A CASE OF HAEMOCHROMATOSIS.

BY

S. LINLEY HEALD, M.D., F.R.C.S. EDIN.,

HONORARY PHYSICIAN TO THE COVENTRY AND WARWICKSHIRE
HOSPITAL, COVENTRY.

I VENTURE to publish this short account of a case of haemochromatosis for three reasons: (1) It was possible to obtain a fairly accurate clinical history of the patient's previous illnesses and of the onset of the fatal disease. (2) The clinical data observed during the last stages were interesting. (3) It seems to me that the case opens up now ground in connexion with this somewhat rare disease.

G. H., a man aged 42, was brought up on a farm, and was one of a large and healthy family. As a child he had a severe attack of scarlet fever, followed by acute haemorrhagic nephritis, which completely cleared up. At the age of 25 he was athletic, well developed, and active physically and mentally. He was appointed works manager in a large engineering firm at the age of 27. His complexion was always sallow (olive), and this colour was universally distributed over the whole skin. On one occasion, fifteen years ago, whilst bathing, this discoloration of the skin was markedly noticeable and was joked about. Five years ago, at a large daylight meeting in a neighbouring town, his doctor, who was acting as door-keeper, on looking up at the gallery noticed his patient's face stand out as a greenish-yellow blotch amongst all the others. His health remained fairly good, except for occasional attacks of dyspepsia, which were characterized by sleepiness and heaviness in the morning, but as far as I can gather were not accompanied by abdominal pain or vomiting. On one occasion calomel was prescribed and acted with extraordinary vigour.

In 1916 an abscess developed on the dorsum of the right foot. This was followed by other abscesses in various parts of the body, and finally by a prostatic abscess, which burst into the rectum. *Bacillus coli* was found to be the causative organism, and he was treated by vaccines, which did not, however, prevent other abscesses developing. The discoloration of the skin varied in depth according to his general health, becoming much lighter after a month's holiday. It may be mentioned that he always took "Fellows' syrup" as a tonic when he felt run down, but I have no data as to the effects of this substance upon the pigmentation of the skin.

In December, 1921, he first consulted me because he felt tired after exercise, and had insomnia, and cramps in the legs. Examination showed nothing abnormal, except that the liver extended 1½ inches below the costal margin, the edge being hard and well defined. The spleen was not palpable. It was easy to examine the abdomen as the muscles were not at all rigid. The urine contained 7 per cent. sugar, but no albumin, acetone, or diaceto-acetic acid. He was gradually dieted down to meat, eggs, green vegetables, butter, and 4 oz. of bread daily; but the urine

still contained about 7 per cent. sugar, and the quantity was 5 pints daily. He then went to an institution for treatment, where he stayed about three months. The report on admission was as follows: "Height 5 ft. 11½ in. Weight 11 st. 2 lb. Pale, thin, and tired-looking. Pulse 68. Systolic blood pressure 114 mm. Hg. Blood .90 per cent. Hb; red cells 4,450,000 and white cells 3,200 per c.mm.; blood sugar, 0.34 per cent. Faeces normal. Urine (twenty-four hours) 2,856 c.cm.; specific gravity 1035, acid, sugar 157 grams, traces of acetone and aceto-acetic acid, Albumin, a faint trace." The fat was restricted and followed by a two days' fast in bed; a little protein was then allowed for three days, followed by another fast for two days. After the second fast the urine was sugar-free. Food was then allowed, starting with proteins only. Glycosuria returned with 80 grams protein, 3 grams carbohydrate, and 3 grams of fat. The diet was gradually increased, the fat and carbohydrates being kept low and a fast day instituted once a week. On this régime the sugar in the urine fell to a trace on the fast day, rising to 100 grams by the end of the week. The blood sugar fell to 0.19 per cent. during the fasting; subsequently it varied between 0.24 and 0.40 per cent. There was no appearance of acetone or aceto-acetic acid. On leaving the institution his weight was 9 st. 10½ lb., a loss of 19½ lb. His thirst had almost gone, and he felt stronger. When he returned home his teeth, antra, and sinuses were examined, but no septic foci were discovered.

In April, 1922, the liver was markedly enlarged, to the level of the umbilicus, hard, with signs of lobulation in the epigastric area. The spleen was easily palpable. From this time until his death in June, 1922, the urine was repeatedly examined for acetone and aceto-acetic acid, but the result was always negative, despite the fact that for the last two or three weeks he was in a semi-comatose condition. During this time darkish pigmentation appeared, chiefly round the elbows and on the hands. The following diet and urine chart may be of interest:

	Carbo- hydrate.	Protein.	Fat.	Urine.
	Grams.	Grams.	Grams.	
April 6th	30	193	42	6½ pints; 2.8% sugar.
April 18th	42	201	54	7½ " 5% "
May 12th	14	185	19	7 " 6% "

He was now allowed 40 grams of white bread daily, and later this was increased to 60 grams, together with 5 oz. of milk. After the semi-comatose condition was established he practically lived upon skimmed milk and soda-water. He became gradually weaker, and died from exhaustion on June 8th. He was quite conscious just before his death.

A complete post-mortem examination was out of the question, but a portion of skin from the back of the hand was examined and showed a well-marked reaction for iron. The dark pigmentation was most marked over the backs of the hands, the elbows, and shins, and on the genital organs.

I desire to thank Dr. J. Orton of Coventry and Dr. A. P. Thomson of Birmingham for their valuable help in writing this short record of the case.

I would draw attention to several points in this case which strike me as being particularly interesting.

1. Did the attack of nephritis in childhood, which cleared up, have anything to do with the subsequent disease? Could it have left the kidney uninjured except for difficulty in excreting iron?

2. The fact that the patient's colour altered considerably at different periods appears to show that if this disease is due to loss of renal excretion of iron, then the loss is not total.

3. Although in a semi-comatose condition with a glycosuria of 7 per cent., there was no sign of aceto-acetic acid or acetone in the urine. I think we may presume that the pancreas was almost totally destroyed; if so, then there must be some other unknown cause for the presence of acetone in the urine of ordinary diabetics.

4. Cases of haemochromatosis are probably more common than we think, and could be diagnosed at an early stage after the peculiar colouring of the skin has become noticeable. I have no doubt that careful dieting would enable them to live for longer periods, and useful lives might be prolonged.

THE late Mr. A. D. Serena, of York Terrace, Regent's Park, who left net personality of £374,214, bequeathed £10,000 free of duty to the London Hospital. After paying certain legacies the remainder of the estate is to be divided among some forty-four charities, including the following hospitals: London, Charing Cross, King's College, Guy's, Middlesex, University College, Royal Free, St. Bartholomew's, St. George's, St. Thomas's, St. Mary's, Royal Northern, Royal Hospital for Incurables, Poplar Hospital for Accidentals, Hospital for Consumption and Diseases of the Chest, Fulham Road, Cancer, Chelsea Hospital for Women, Queen Charlotte's Lying-in Hospital for Sick Children, Great Ormond Street, Lock Hospital, Harrow Road, and the Italian.

NINETIETH ANNUAL MEETING
OF THE
British Medical Association.

Held at Glasgow, July, 1922.

PROCEEDINGS OF SECTIONS.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Professor G. M. ROBERTSON, M.D., F.R.C.P.Edin., President.

PRESIDENT'S INTRODUCTORY REMARKS.

THE PRESIDENT, in opening the proceedings, deplored the separation of neurology and psychology, which was disastrous for both, and welcomed the combination of the Sections at the present meeting. Psychotherapy came to the fore during the war, the public taking a great interest in it, and the medical profession should express itself clearly on the subject. Psychotherapy was the oldest form of treatment—the methods of cure in the Bible were psychotherapy pure and simple; the successful medical man was the successful psychotherapist, though he might not know it.

DISCUSSION ON PSYCHOTHERAPY.

OPENING PAPERS.

I.—PSYCHOTHERAPEUTICS AND PSYCHOPATHOLOGY.

BY

T. W. MITCHELL, M.D.,
Hadlow, Kent.

DURING the war and in the years that have passed since its close, much interest, both popular and scientific, has been shown in the principles and practice of psychotherapeutics. Newspaper accounts of lightning cures of "shell-shock" soldiers, effected by means of suggestion or persuasion, excited the popular imagination; reports of the beneficent results of "abreaction" and the reassociation of lapsed memories gave rise to a considerable amount of discussion in medical and psychological circles; and the widespread acceptance of "repression" as the cause of mental dissociation gave rise to the erroneous belief that psycho-analysis was extensively used in the treatment of the war neuroses. The general public—and, indeed, a not inconsiderable number of the medical profession—became hopelessly confused; for the most responsible newspapers in the chief city of the empire promulgated day by day the wildest nonsense regarding the doctrines and the practice of psychotherapeutics.

It is hardly our business here to correct the false impressions thus produced on uninstructed minds, but a meeting of this Section affords a good opportunity of discussing among ourselves the principles and methods of psychotherapeutics and of trying to come to some agreement as to what is and what is not sound theory and good practice.

In the history of medicine the development of rational therapeutics has taken place alongside of, and in closest dependence on, the growth in our knowledge of pathology; and a psychotherapy that is not based upon psychopathology can be little more than pure empiricism. Although the empirical use of psychotherapeutical measures has been practised from the earliest days up to our own time, there are good grounds for thinking that treatment through the mind has at last emerged, or is emerging, from this phase and is now assuming its rightful place as a branch of rational therapeutics. But perhaps this can fully come to pass only when psychopathology is also accepted as a necessary part or aspect of general pathology.

Yet in so far as pathology is a study of the proximate causes of disease, the notion of a psychopathology—which in this connexion implies mental causation of disease—must be a shibboleth to many psychiatrists and neurologists. For they have been trained to believe that all disease, whether of body

or of mind, must have origin in morbid structure or function of the bodily organism; and even those who profess belief in a strict parallelism of neural and mental states—a parallelism which entails absolute concomitance of neural and mental events—seem often to hold, as a sort of overbelief, that neural change precedes the mental change, be it by ever so little, in both normal and psychopathic states.

Those who explicitly or implicitly hold this view would save themselves much inconvenience in their approach to the problems of psychotherapeutics and psychopathology if they would realize that insistence on the invariable priority of bodily change in bodily or mental disorders is an unwarrantable intrusion of metaphysics into the realm of science; and if they are not able, for methodological purposes, to adhere, in thought and language, to a consistent parallelism, they would perhaps do well to use the language of everyday life in their references to the relations of body and mind.

The common sense of mankind has always held that there is a real and close relation between the mind and the body, and it accepts, without question, the causal nature of that relation. It maintains that states of mind are caused by states of body, and that states of body are caused by states of mind. Common sense holds that mind and body interact, one with the other, and in all our conduct this belief is tacitly assumed.

By using the language of everyday life and common sense we are able to consider all departures from health, whether of body or of mind, from the point of view of psychical causation; and we may thus extend, if need be, the sphere of psychopathology beyond that to which it is ordinarily confined—namely, the psychoneuroses and the psychoses. We may, for example, consider seriously the part played by the mind in the causation of many bodily disorders which are not ordinarily regarded as having any other than a purely physical origin. Some justification for so doing is afforded by a consideration of the results obtained in the treatment of these conditions by the various psychotherapeutic measures which are now included under the term "suggestion." The extent to which psychotherapy is of value in dealing with functional and even organic bodily disorders is perhaps not fully appreciated, except by those who have made extensive use of suggestion in general practice.

It is commonly assumed that, if any mental or bodily disorder can be relieved by influences acting through the mind, the mind must have played a part in the production of such disorder. But if we believe in the possibility of a true interaction between mind and body such an assumption is unnecessary, and we may suppose that, just as bodily disorders lead to mental states, such as depression, so mental states, such as joy, lead to bodily well-being.

The facts in support of the assumption that what is relieved through the mind must have had its origin in the mind are mainly derived from our knowledge of conversion hysteria, and of the efficacy of suggestion in relieving the physical symptoms of this malady. But generalization from the results obtained in these cases, and assertion that these results are identical with those obtained in cases in which the existence of conversion hysteria has not been suspected, may be wholly unwarranted; and by too ready acceptance of such a generalization we may miss something that is of real importance regarding the relation of mind and body in health and disease.

If it be true that relief of a bodily symptom by psychotherapeutic measures is proof of the psychogenetic origin of such symptoms, or of the presence of conversion hysteria, our experience of the use of hypnotic suggestion, in cases of all sorts met with in general practice, would compel us to come to some strange conclusion regarding the prevalence of conversion hysteria. If every symptom that can be relieved by suggestion is evidence of the presence of hysteria, then it must be believed that 80 to 90 per cent. of our patients in general practice are suffering from hysteria.

Let us take an example: there is perhaps no more common instance of faulty bodily functioning than habitual constipation; and the cure of this condition, by material remedies alone, is perhaps impossible. On the other hand, almost every case of habitual constipation in which hypnosis can be induced may be cured by suggestion without the use of any material remedies whatsoever. Or, take another example; an apparently healthy young woman gets badly scalded by the upsetting of a kettle of boiling water. The wound is appropriately dressed and, during

hypnosis, absence of pain and rapid healing are suggested. There follows a sequence of events frequently recorded in experimental work on hypnotic suggestion: no pain is experienced, no inflammatory area develops, and the injured part heals with unusual rapidity.

In dealing thus with a burn the injured part is kept at rest and it is protected from morbid agencies from without by appropriate dressings. But the securing of such rest and protection is perhaps the sole biological function of pain and the reason for its arising in the course of mental evolution; and when this necessary condition of healing can be secured in other ways while pain is eliminated by suggestion, we get a better result than we do when the same precautions are taken but pain is experienced. It would seem as if the processes involved in the production of the pain which in a state of nature is necessary to ensure protection and rest of the injured part were in themselves inimical to the healing process.

Here, then, we have two examples of the part played by mental influences in effecting bodily changes which can hardly be claimed as instances of conversion hysteria. I refer to them because at the present time there is a tendency to forget the work of the hypnotists in the treatment of functional bodily disorders, and to judge the value of suggestion as a therapeutical agent by the transitory effects of its use in the psychoneuroses. Indeed, for many, the psychoneuroses seem to constitute the only domain in which psychotherapeutic endeavour is justifiable or effective; and if the field of psychotherapeutics is thus restricted there is some danger lest the forms of psychotherapy most useful in dealing with the psychoneuroses may be regarded as the only valid psychotherapeutic measures, while those that are of little or no value in the psychoneuroses may be declared useless in all conditions whatsoever.

There are two circumstances which are especially conducive to these errors at the present time. It must be remembered (1) that many of those who are now practising psychotherapeutics had little or no knowledge of this branch of treatment prior to the war, and (2) that practically all the war cases they were called upon to treat were cases of neurosis, psychoneurosis, or psychosis. And in the years that have passed since the end of the war these workers have probably had little opportunity of testing the value of psychotherapeutic measures in any conditions other than these. Their views on theory and on practice are thus apt to be unduly biased by their war experience; and because of the mere numbers with which they had to deal they are prone to generalize too freely in respect of the use of psychotherapeutic measures in civil practice.

Much of the treatment by suggestion in recent years has not, however, been "hypnotic suggestion"; that is to say, no formal attempt to induce hypnosis is made before curative suggestions are given to the patient. A state of rest and relaxation is considered sufficient for this purpose, and it is commonly held that the results so obtained are not inferior in any way to those recorded by the exponents of hypnotic suggestion. Moreover, many men who practise psychotherapeutics have never been able to reconcile themselves to the formal use of suggestion, even apart from the employment of hypnosis. They have felt that it savoured too much of the quack or the miracle worker, and they have been doubtful of the value of any method which brings about faith or belief without an appeal being made to the patient's reason or intelligence. Consequently we find that therapeutic systems in which chief stress is laid upon persuasion and re-education of the neurotic patient have been widely adopted; and since it was found that when such appeal to the reason is made results are obtained which are as good or better than those recorded by the hypnotists, it was thought that the appeal to the reason is the essential feature of this method, and that the patient's recovery is due to his rational acceptance of the explanation given by the physician.

But we know that the explanation given to the patient need not be the true one; what is necessary is that the patient should believe it to be the true one. Failure or success depends on the extent to which the physician is able to instil faith into the patient's mind, just as is the case in all forms of suggestion. Indeed there can be no doubt that treatment by persuasion is treatment by suggestion, and that even the benefits derived from re-educative efforts are largely due to the same subtle influence.

In order to give to the patient any reasonable explanation some greater degree of investigation into the nature and

origin of the illness than is necessary for treatment by suggestion has to be undertaken; and this fuller inquiry may in itself have a certain curative influence, both by the increased confidence or faith in the physician, engendered by the meticulous care with which he examines his patient, and also by the opportunities offered to the patient of giving vent to emotion in his recapitulation of the events that have led up to his illness.

But the most important clues to the origin and nature of the illness are not within the patient's power of conscious recollection, and, just in so far as they cannot be recalled, the physician's knowledge of the malady is incomplete and his explanations inadequate. In the treatment of the war neuroses it was soon found that suggestion or persuasion was often a very unsatisfactory mode of treatment and, in the common psychoneurotic disorders in which amnesia was the most prominent accompaniment of the physical disability or mental disturbance that incapacitated the soldier for duty, it was generally found necessary to adopt some other means of restoring him to health. The importance of reassociation of the dissociated memories was quickly perceived, and hypnosis as a means of discovering them, and suggestion as a means of restoring them to consciousness, were very widely used.

Some workers revived Breuer's method of abreaction and they believed that the freeing of repressed emotions thus secured played an important part in the restoration of lost memories to consciousness and in the consequent recovery of the "shell-shock" soldier. On the other hand, some workers got equally good results by bringing about reassociation of the dissociated memories without any display of abreaction. Thus it would seem that the essential feature of treatment by abreaction is the overcoming of the amnesia which is so prominent a symptom in traumatic psychoneurosis.

In thus directing therapeutic efforts towards the annulment of the mental dissociation which reveals itself in amnesia, an approach is made towards a rational treatment of the psychoneuroses. For we have here that correlation between pathology and therapeutics which is the distinctive mark of scientific as opposed to merely empirical modes of treatment. In using suggestion in the form of mere denial of the symptoms or prognostication of their speedy disappearance, our procedure, although it may be effective, has no rational foundation; or if it appears to have some rational basis, this is due to a false or superficial conception of the psychopathological processes at work in the production of psychoneurotic symptoms. It is true that if we believed with Babinski that all hysterical symptoms are due to "bad" suggestion it might seem reasonable to counteract its consequences by giving "good" suggestion (or, as he would call it, persuasion); but very little knowledge of the psychopathological mechanisms concerned in the production of hysteria is sufficient to convince us of the superficiality of Babinski's views. On the other hand, the conception of mental dissociation which we owe to Janet is of outstanding importance in psychopathology, and its validity is now almost universally accepted. Indeed, it may be said that dissociation is the most fundamental conception in psychopathology, and that the restoration of lost memories is the ultimate goal of all psychotherapeutics.

There would appear to be no conditions in which the occurrence of dissociation might be more readily accounted for than in the neuroses of war. For the strain and stress of life in the trenches, or the shocks and calamities of battle, would indeed seem sufficient to disintegrate the most stable of minds. Janet has taught that dissociation is due to lack of mental synthesis consequent upon a lowering of nervous tension; and if the shocks or stresses of civil life are sometimes sufficient to cause a lowering of nervous tension and a consequent retraction of the field of consciousness, how much more readily would the conditions of modern warfare tend to bring about such a result! And yet we know that almost all those who dealt with the war neuroses on psychological lines accepted the Freudian doctrine of mental conflict and repression as being the immediate cause of dissociation, and that they laid little stress upon the factors described by Janet.

The failure of suggestion, persuasion, and abreaction in the more severe war cases which were treated in the home hospitals constrained medical officers to examine more closely the nature of the dissociation present in those patients and the factors concerned in its production. For the incidence of dissociation—the mental material on which it bears—varies greatly in different psychopathic states. In the war neuroses to which the method

of abreaction was most commonly applied. dissociation was, as a rule, a dissociation *en masse* of a more or less definite section of conscious experience. All the experiences of a day or a week or a month or a year became disrupted from the conscious personality, so that the memories related to them could not be recalled; but in many psychopathic disorders the dissociation is of a more discrete character and the elements on which it bears are bound together by associations more subtle than those that depend upon mere contiguity in time.

When there is dissociation *en masse*, of recent origin, hypnosis is always very easily induced and the lost memories may arise spontaneously or be readily recalled in the hypnotic state. By suggestion or other technical devices they may be carried over into the waking state and become reassociated with those of the normal personal life. But when manifest amnesia is not a prominent symptom in the psychoneuroses, no such dissociation *en masse* is to be found. It is not, however, to be supposed that dissociation and amnesia are not present; the dissociation is there, but it is of a more complex nature; its origin is more remote and is more deeply rooted in the past. In these cases the induction of hypnosis may be more difficult; and, when hypnosis can be induced, it is found to afford little insight into the nature of the amnesia, and to give little assistance in relieving the psychoneurotic disabilities which are present.

In the treatment of many war cases of this kind some sort of analysis of the mind of the patient was seen to be necessary, and, since there was already in existence an extensive literature in which the use of mental analysis of some kind or another was described, it was to be expected that war workers would take advantage of their opportunities of testing the various methods and theories put forward by different schools. This, to a very large extent, they did, and we have had records of mental analyses, some of which were nothing more than a detailed anamnesis; some in which the conscious recollections were supplemented by memories revived during hypnosis; some in which the word-association test was used to set the investigator on the track of some buried complex; some in which the methods of psycho-analysis were more or less consistently employed; and some in which these methods were transcended and the data obtained by their use reinterpreted in the light of mythology and religion.

Behind all this activity in the domain of mental analysis, and overshadowing it, stood that body of doctrine associated with the name of Sigmund Freud. The great majority of the war workers in psychotherapeutics could not get away from it and they could not accept it. The truth of some of the tenets of the Freudian school was borne in upon all competent investigators, including even some of the neurologists. The psychogenetic origin of the war neuroses was by many reluctantly conceded; the principle of mental dissociation was widely accepted; the psycho-analytical doctrine of neurosis as a "flight into sickness" with a view to satisfactions that could only thus be obtained was readily adopted—perhaps because of its seeming agreement with the popular notion that all neurosis is malingerer, rather than as a well-attested scientific hypothesis. But what seemed to me the most striking feature of the psychotherapeutic practice of war workers was the extraordinary unanimity shown regarding Freud's theory of repression, combined with a rejection of almost the whole body of doctrine erected on this foundation by Freud himself. The seemingly clear demonstration afforded by a superficial analysis that the traumatic neuroses of war could be adequately accounted for in terms of mental conflict and repression in which instincts other than those called sexual by the psycho-analysts were alone concerned led many able men to the logically untenable conclusion that the *libido* theory of the neuroses was thereby proved false. A strange eagerness was shown in bringing forward this conclusion. It looked as if those who upheld it thought there was some special virtue in dissociating themselves from a sexual etiology of the neuroses. We had the strange spectacle of men of science apparently being influenced by the notion that one explanation of any natural phenomenon may be more respectable, or ethically more worthy, than another—a strange spectacle, but one not unique in the history of science. We may call to mind the reception given to Darwin's theory of the origin of species: the contemporary records of the discussions initiated by the epoch-making hypothesis of natural selection bear a strong resemblance to those of our own time regarding Freudian doctrine. Psycho-analysis throws an

illuminating light upon the mental processes at work in uncritical rejection of what ultimately may prove to be scientific truth. In science, more truly than in life, we see the force of the poet's contention that "they were dangerous guides, the feelings"; and of each of us it may have to be said that, at some time or another, he himself "was not exempt."

Yet if we can overcome our resistances to the *libido* theory of the neuroses, if we can bring ourselves to examine dispassionately the evidence on which the theory has been built up, we cannot fail to see and be astonished at the light that it throws upon the psychology of abnormal mental states and the order and coherence that it brings into a department of pathology hitherto characterized by obscurity and confusion. For, quite apart from all consideration of psycho-analysis as a therapeutic method, its painstaking examination of the neurotic mind has brought us at last a genuine psychopathology in which the morbid structure of the psychoneuroses is laid bare and the processes by which their development takes place are revealed. It must be remembered, however, that all the most definite and best established formulations of psycho-analysis have been obtained from the study of the transference neuroses—conversion hysteria, anxiety hysteria, and compulsion neurosis—and that the application of the *libido* theory to the psychoses and to the traumatic neuroses has only recently received adequate consideration. Such progress as has already been made has been rendered possible by the recognition of the part played by *narcissistic libido* in the production of these states.

There are various grounds for the opposition which so many people feel towards the doctrines of psycho-analysis, and some of these grounds may be made more clear and their validity may be more justly appraised if we draw a distinction between psycho-analysis as a method of investigation in psychopathology and psycho-analysis as a therapeutic measure. For it may reasonably be maintained that the aims of pathology and the aims of therapeutics are different, and that our criteria of values may change according to the ends we have in view.

If we can bring ourselves to study the structure of a mind that has gone astray in its development, without any feelings of responsibility towards a fellow creature in distress who has sought our aid, we can, without compunction, adopt the purely scientific attitude which the pathologist brings to his work in the *post-mortem* room or the physiologist to his experiments on an anesthetized animal. But the psycho-analyst as a therapist, unless he is quite sure of himself and of the validity of his methods, is rather in the position of a surgeon about to perform a major operation for the first time. He can hardly refrain from thoughts of the possible outcome of his work; he cannot avoid feeling that the life or well-being of his patient is in his hands; he cannot help being oppressed by his responsibility towards one who has trusted him and turned to him for help. And just as considerations of these kinds may stay the hand of the surgeon from operative procedure which is too risky, so the psychotherapist may regard as a violation of the patient's mind those investigations which as psychopathologist he might ardently wish to make.

Here we have what appears to me to be the chief difference between the standpoint of the man of science as mere investigator and the same man as therapist, and the difference in these standpoints may account to some extent for the different considerations which may affect his attitudes or beliefs, in respect to psycho-analysis, according as he approaches the subject in the one rôle or in the other.

If we take, for example, that feature of the Freudian psychology which more than any other has aroused opposition—namely, the supreme importance ascribed to psycho-sexual tendencies in the life and growth of the mind—there would seem to be no reason why a psychopathologist, in the seclusion of his study, should not readily recognize a truth for which all his biological training must have in some degree prepared him. But if it is a question of his making use of the truth so realized and of applying it in the treatment of the neuroses, there are many powerful forces at work in his mind which may not only prevent him from doing so, but may even compel him to repudiate the truth which, for a moment, he had clearly discerned.

But although there would appear to be no reason why a feeling of repugnance, yet we know, as a matter of fact, that all men have resistances against bringing

into the light of day that side of human nature which morality and religion have decided shall be taboo; and not until we have overcome these resistances are we able to take up an objective attitude towards the doctrines of psycho-analysis. It seems to me, however, that it is easier to overcome resistances to psycho-analysis as a body of doctrine than to its use as a method of therapeutics. The truth of this is perhaps exemplified in the attitude taken up by Jung and his followers towards psycho-analysis; for they seem to accept the truth of its psychopathological findings while they deny that it is a justifiable or efficacious therapeutic measure.

There is one curious ground of objection to psycho-analysis which has not infrequently been put forward—namely, its insistence on a "thorough-going determinism." And here again, I think, it may be useful to consider this objection from the side of the psychopathologist on the one hand and from that of the psychotherapist on the other. The psychopathologist is a man of science, and *qua* psychopathologist he has no temptation to be anything else; but the psychotherapist may feel it incumbent on him to play the part of a moral or spiritual director to his patient. To the man of science determinism is a necessary postulate of all his investigations: the reformer and the priest cannot abandon belief in human freedom without stultifying all their precepts.

The psychopathologist can therefore have no possible ground of objection to psycho-analysis because of its determinism; on the contrary, it is the strictly determinist standpoint of the psycho-analyst which alone makes it possible for his findings to be regarded as suitable material for scientific study. It may be pointed out, however, to the analyst who feels the need to retain his belief in freedom, that he also may accept the determinist standpoint in his examination of a patient's past mental history, however much he may believe in the indeterminateness of its future. For even if we admit the reality of the freedom of choice which our moral nature demands, "we can confidently lay it down that no event will ever occur which will not seem intelligibly connected with its antecedents *after it has happened*."

The psycho-analyst's insistence on the determinism of psychic events is primarily an insistence on the plea that the methods of science are applicable to the study of the human mind. But there is no need whatever to raise the metaphysical problem of the freedom of the will in regard to psycho-analysis as a branch of science. Freedom is a postulate of ethics: determinism is a postulate of science; and no good can come of trying to introduce ethical or moral considerations into the purely scientific investigation of the mind—a tendency at present all too common in relation to psycho-analysis.

Many men have been heard to express strong convictions regarding what they believe to be the errors of psycho-analytical theory and the failure of psycho-analytical practice; but as Freud himself says:

"No one has a right to convictions on these matters who has not worked at the subject for many years, as I have, and has not himself experienced the same new and astonishing discoveries." "If owing to ignorance of the subject you are not in a position to adjudicate, then you should neither believe nor reject."

II.—THE MAKING OF A NEUROTIC.

BY

J. A. HADFIELD, M.A., M.B., CH.B.,
London.

WE shall discuss this subject of "The making of a neurotic" in three phases:

1. The formation of the morbid complex.
2. The conflict of complexes.
3. The emergence of the symptom.

The Formation of the Morbid Complex.

The psychoneurotic symptom, like every form of animal behaviour, normal and abnormal, is ultimately the result of two factors, the hereditary and the environmental, and of these the determining factor is the environmental. Modern methods of investigation go to show that we do not inherit

psychoneurotic symptoms, but that these can always be traced back to environmental influences during the lifetime of the individual. Before the early years of life could be investigated by hypnotic and analytic methods it was quite natural to assume that all neuroses which had existed from earliest childhood were due to hereditary or congenital causes. If a patient said that he had had his symptom "all his life," or "as long as he could remember," it was considered sufficient to assume that he was born with it. But many things happen in the first three or four years of life which a patient does not remember, but which have an important influence on his life and conduct. Now that those early years of life have been explored and laid bare by hypnotic and analytic methods it has been found that many conditions—neurotic headaches, bad temper, cynicism, alcoholism, homosexuality—formerly assumed to be congenital, are really due to abnormal environmental conditions of early childhood. It is true that many characteristics, normal or morbid, may be transmitted from father to son, but where such transmission takes place it is found to be not by way of inheritance, but by means of suggestion, sympathy, and imitation. The same law seems to operate in the psychoneuroses as in a disease like tuberculosis—one may inherit a predisposition, one cannot inherit the disease. Let us take an illustration.

A man has a tremor of the hand, which dates back "as far as he can remember"; indeed, his father had it before him, and the condition was put down to some inherited condition of the nervous system. On reductive analysis it was found to have originated when as a child of 3 years he was badly injured in the foot and was held down by his father while the doctor probed his wound. The trembling of his father's hand transferred itself to the son's and was associated with this painful emotional experience. This condition, like many another which was presumably inherited, was found to be due to a complex formed during the life of the individual, and was consequently cured.

As we should never diagnose hysteria until we have excluded organic disease, so we should never assume hereditary or congenital causes until we have excluded the environmental origin.

The psychoneuroses are thus to be clearly distinguished from "mental deficiency," which is commonly congenital or hereditary, and in any case is the direct result of a physiological deficiency of nervous structure. The psychoneuroses are psychogenic, and originate in abnormal psychological experiences during the life of the individual. It is true that in practice one meets with many neurotics who are also mentally deficient, inasmuch as they have inherited some physiological abnormality whether cortical or endocrine. (Indeed it is reasonable to assume, though I am unaware as to whether it is the fact, that such defectives are more liable to suffer from the psychoneuroses than others.) But this is not necessarily the case, for there are undoubtedly many patients suffering from the psychoneuroses who have not the slightest trace of mental deficiency, nor any trace of the stigmata of degeneration, but whose psychology is nevertheless distorted and gives rise to morbid symptoms.

Nevertheless, in the psychoneuroses hereditary factors do play an important part. Although we do not inherit a neurosis, we may inherit what is commonly called a "nervous temperament" or a "highly strung disposition," which is probably dependent upon a physiological condition of the synapses, of the endocrines, or perhaps of both. But a highly strung temperament is not a disease; everything depends on what we make of it. Thus in one family in which both parts are of a nervous temperament you may find one son an artist, one a poet—who commits suicide—one an alcoholic, and one a great preacher. The highly strung person is more sensitive than others to the pains and responsibilities of life, but he is also more sensitive to its joys and beauties. Besides this physiological factor of the nervous temperament we have the psychological factor—namely, the instincts, and it is these which play such an important part in the formation of complexes and therefore of the psychoneuroses. McDougall has emphasized that every child is born endowed with a number of instincts, each of which is charged with emotional tone—fear, anger, sex, maternal, submission, self-assertion, curiosity, self-display, and others. Shand has shown that when emotional tendencies are brought into touch with environmental conditions they tend to become attached to the objects which arouse them. These two factors combine to form mental experiences which

are retained in the mind as *psychological constellations*. Each constellation therefore consists of a nucleus from the environment—whether a person, event, or idea—round which are grouped or constellated the instinctive emotions. For instance, the sentiment of patriotism is formed by the attachment of all our instinctive emotions of admiration, tenderness, fear, pugnacity, submission, and assertion to our country.

There are three forms of psychological constellations: sentiments, dispositions, and complexes, the last of which give rise to the psychoneuroses.

The *sentiments* are those constellations which are consciously acceptable to us, and with which we consciously identify ourselves, like patriotism, the mother sentiment, the religious sentiment, and the sentiment for others, or altruism. The most dominant of all our sentiments are what we call our aims or ideals, since they are capable of moving our will to endeavour.

Psychological dispositions are those constellations which are so accepted by us that their activities become spontaneous and automatic. We are said to be "disposed" to this idea or that, or to this or that person, when our instinctive emotions are attracted towards them; so we develop a kindly disposition, a stoical, cruel, cynical, or egotistic disposition. Together the various dispositions in us combine to form what we term our "disposition." Psychological dispositions are the main constituents of character and the source of most of the normal habits of everyday life.

Dispositions differ from the sentiments in that they are unconsciously accepted, their activities are spontaneous, so that to act in response to them is "second nature" to us. An Englishman does not need to think whether he choose to save himself or his child in a wreck—the decision is spontaneous; he has a disposition of honour.

Dispositions are to be distinguished from such as give rise to habits like *physical* dispositions like the instincts, for they are formed of instincts attached to ideas or objects.

Our psychological dispositions, together with the sentiments—that is to say, all those constellations which are acceptable to the individual—are together combined and organized to form the "*organized self*." When we normally speak of our "self" we mean all those sentiments and dispositions of which we approve and with which we identify ourselves. The function or activity of the "organized self" is the will.

The *complexes*, like the sentiments and dispositions, are formed by the attachment of the instinctive emotions to objects or experiences presented by the environment. But because of their repugnant or painful nature they are rejected by the self as unacceptable. The thought of the war may be the nucleus of a sentiment to a man who was heavily decorated, a complex to a man court-martialled for cowardice. Again, what at one age may be a mother sentiment may be a mother complex at a later age. Complexes are commonly named according to the dominant emotion contained in them, like a "fear complex," "sex complex," "inferiority complex," or at other times by the name of the nucleus round which the emotions are grouped—a "mother complex," or "war complex," or "religious complex."

Complexes may be consciously recognized. Acts of cowardice, humiliation, or a sex trauma may be remembered only too well in spite of our endeavour to forget all about them. But many complexes are unrecognized. As we may dissociate ourselves from friends who have insulted us, or refuse to associate or identify ourselves with those who have disgraced our family, so we may "cut" and refuse to recognize or identify ourselves with complexes which are repugnant; they then become dissociated, split off, forgotten, until we become quite unaware of their existence. This process of dissociation being an active one, the term "repression" is found to be the more appropriate to describe it.

Sometimes all that is recognized of a complex is the nucleus or some accidental element in it. This is the case where there is a functional paralysis or a fixed idea which emanates from an emotional complex, but in which only the idea or physical symptom emerges while the emotion associated with it remains repressed. At other times it is the emotional element which is recognized, while the nucleus remains unrecognized. This is so in "anxiety" states, in which there is a fear, but the object of the fear is unrecognized. When the complexes are recognized and are con-

sciously inhibited from expression in conduct we call it *restraint*; when the process of inhibition is unconscious we call it *repression*. It is important to recognize this distinction.

The dispositions and complexes are the sources of all our psychological "habits" normal and abnormal, the dispositions giving rise to what we term "good habits," like that of cleanliness, and the complexes "bad habits," like tipping or the neuroses. Complexes may thus be recognized or unrecognized, consciously restrained or unconsciously repressed. The former, the recognized complex, may affect our character and happiness; the latter, the repressed complexes, are alone capable of producing a psychoneurosis. The activity or function of the organized self we call the will; the manifestation and activity of the complexes we call impulses.

There is thus formed an antagonism in the mind between the will and impulses, between the "self" and the complexes, for their aims and ends are antagonistic to one another. As long as this antagonism remains, there is unhappiness and there may be neurosis. But complexes may be antagonistic not only to the organized self as a whole but to one another, for the ends of each complex are different from and often opposed to one another. Thus the fantasy of being a hero conflicts with a fear complex; self-display or exhibitionism with a localized adult form of sexuality.

Thus there are two forms of conflict—that between the self on the one side and the complexes on the other, and a conflict "in the unconscious" between repressed complexes. We shall later observe that a psychoneurotic symptom does not arise from one repressed complex, but from a conflict between repressed complexes. We shall also have reason to observe that the symptom serves the purpose of satisfying both sides of the conflict by giving expression to both complexes, and not merely to one complex.

Of all complexes none are more important than those which are concerned with the self—the fantasies of oneself which develop in early life. It has long been maintained by psycho-physicians that the psychoneuroses originate in the first five years of life by trauma, suggestions, imitation, the atmosphere in which we are brought up, or other influences. I am inclined from personal experience to limit the time still further, and to say that all neuroses develop in the third or fourth year of life. For it is in the third or fourth year that every child develops self-consciousness—that is to say, gets its first impression of itself; and this impression, false or true, fantastic or real, is destined to remain with him and affect his whole life and character thereafter. The fantasies a child develops about itself from suggestions of its environment are of infinitely greater importance than any traumatic "shock." If a child is excessively admired it develops a fantasy of self-display, such as this fantasy from an artist: "There is nothing on God's earth perfect but me." A child pampered and spoiled, having everyone—mother, nurse, aunt—at its disposal to do its bidding, develops a fantasy of self-importance and omnipotence; another, neglected, kicked, and bullied, develops a fantasy of inferiority and self-depreciation; another has the fantasy of moral snobbishness, and in later life becomes a censor of others; one a fantasy of infallibility, and in after-life "can't do wrong," but blames others for its faults; another of omniscience, and becomes dogmatic; another is "perfect," and therefore intolerant of criticism.

It is true, indeed it is in the nature of the case, that such fantasies are unrecognized and are formed into repressed complexes. Our conscious conception of ourselves is often the opposite of our unconscious fantasy.

I once asked a distinguished artist if he had a fantasy of self-importance. "Not at all," he said; "I think much less of myself than I really am." The business man of 50 who comes with a breakdown, with the sense of failure and lack of confidence, is commonly a man with an extravagant power psychology, although he may consciously conceive himself as the world's greatest failure. Our conscious conception of ourselves is often the opposite of our unconscious fantasy of ourselves. A golfer remarked, "I have played golf for forty years and have never been on my game yet." He had an unconscious fantasy of what "his game" was.

Of all complexes those which are formed as fantasies round the idea of ourselves are the most potent. Indeed, I am inclined to think that they are the only ones that matter. In other words, it may be said that egoism lies at the base of every neurosis as long as we use the term

"egoism" to include not only self-love, self-esteem, self-importance, self-display, and self-righteousness, but also self-depreciation and fantasies of inferiority.

It is not difficult to see how such fantasies produce a nervous breakdown. If a man sets out to conquer the world and conquers only one hemisphere he feels a perfect dud. He is a failure in that he has failed to reach the impossible.

Yet such a fantasy as that I have just mentioned cannot itself produce a nervous breakdown.

The Conflict of Complexes.

Every psychoneurosis is the result of a conflict between two repressed complexes. I have often heard a patient's psychology described thus: "He has a sex complex," or "He has an inferiority complex." It cannot be too strongly emphasized that for the formation of a neurosis two complexes are necessary.

Exhibitionism is the repressed instinct of self-display. If this tendency is exaggerated by circumstances it affects the character but does not cause neurosis; if it is exaggeratedly developed and then rudely repressed, as by a severe punishment, there are formed two complexes, which conflicting form a neurosis. It is true that the man who sets out to conquer the universe breaks down, but why did he want to conquer the universe? This excessive and exaggerated fantasy was developed as an overcompensation for a feeling of inferiority. He was coddled because he was physically weak and developed a feeling of inferiority from which he was ever trying to escape.

If every neurosis is caused by the conflict of two repressed and antagonistic complexes it is of the utmost importance to discover both complexes. In the last case mentioned we need to analyse out not only the circumstances which gave rise to the fantasy of superiority but also that of inferiority. A psychoneurosis is never due merely to a repressed sexual desire, a repressed fear, or feeling of inferiority: it is due to a conflict between each of these complexes and another complex, such as a moral snobbishness, an extravagant sense of duty, or a fantasy of self-importance. Shyness, for instance, is never merely the expression of a sense of inferiority; shyness is the result of a conflict between the sense of inferiority and of superiority. We are never shy unless we are conceited; it is because we are not taken for what we think we imagine we are worth that we feel so shy and inferior.

It is for this reason that it is so frequently the youngest child who develops a neurosis. It is often said that the only child develops neuroses more than others. That is not my experience. I have very few only children to treat. The reason seems clear: the only child is usually brought up in a consistent atmosphere, frequently that of considering itself to be God, and develops fantasies of omnipotence, omniscience, and moral perfection. Such a child is excessively conceited in after-life, but does not often have nervous disorders. On the other hand, a child consistently brought up to regard itself as inferior grows up quite prepared to take a back seat in life. In neither is there an endopsychic conflict. But the youngest child develops two conceptions of himself—for instance, if a child is made to believe itself a prince by its fond parents and a worm by its jealous brothers. Or at one time of life, say for the first three years, it is given its own way and develops the fantasy of omnipotence, and at the next phase, perhaps owing to the death of an overdevoted mother, is excessively suppressed by a godmother or nurse—under such conditions a conflict ensues between the two fantasies, both of which have now become repressed complexes. The individual does not know if it is a god or a worm, and when the moment of decision arrives—on the battlefield, in marriage, or on the Stock Exchange—the patient tries to be both and breaks down.

Each complex is formed as a result of factors of which the environmental is the more important, but the neurosis itself results from an endopsychic conflict between repressed complexes. We can never account adequately for the nervous breakdown, nor can we treat it adequately until we recognize and analyse out both elements in the conflict.

We frankly approach this subject from the psychological point of view. The attitude of the psychologist differs radically from that of the biologist. The biologist looks at life from the point of view of adaptation to environment. The psychologist interprets everything from the point of view of mental processes and is interested in the events of

the objective world only in so far as they give rise to mental processes. The psychologist and the biologist are not in any way antagonistic, but they look at life from different angles. This difference of attitude is of the greatest importance, not only in the conception of the psychoneuroses, but particularly in their treatment.

It used to be thought that a nervous "breakdown" could be caused by an objective experience, like a "shock," a fright, a sexual trauma, a disappointment, a failure. Man's main function in life, it was said, was to adapt himself to his environment, and a nervous breakdown was said to be due to man's failure to adapt himself to his environment. The soldier, it seemed quite obvious, breaks down because he cannot adjust himself to the strain and stress of war, and the girl to the shock of the sex trauma, the business man to his failure in business. This is all perfectly true from the biologist's point of view, but not from the point of view of the psychologist, and it is an inadequate conception from the point of view of treatment. If a soldier's breakdown were merely due to his failure to adapt himself to his environment he could easily overcome the difficulty by running away to safety. Why does he not do so? Because there is something within him preventing his doing so; he fears being a coward more than he fears the shell fire. In other words, a man's nervous breakdown is not due to the failure to adapt himself to his environment, but his failure to adapt himself to himself. The real conflict, a conflict more important than that between himself and his environment, is that between his courage on the one hand and his fear and desire for self-preservation on the other. It is quite true that the shell fire is the exciting cause, but it is effective only in relation to what it excites—namely, fear—and gives rise to a mental conflict. He has failed to accommodate himself to those latent forces of fear which his courage and sense of duty refuse to recognize. Running away is no solution to such a problem, whereas it would be if it were merely a matter of adaptation to environment. He, therefore has to resort to a nervous breakdown to deliver him from the conflict.

The "shocks" which produce the psychoneuroses are always shocks we give ourselves. Stated in terms of psychotherapy, the psychoneurotic symptom is always the result of an endopsychic conflict.

This psychological approach to the neuroses is of the utmost importance in treatment; our problem is not primarily to fit a man to face his environment, but by discovering both elements in the conflict to fit him to face himself. For a man is impotent to face the onslaughts of the objective world until he has restored peace in the borders of his own soul; only when he has resolved these conflicts in his soul is he fitted to face his environment. He is then capable of facing the most terrible experiences, as has been proved by the many thousands of men who have braved the Arctic snows and stood the storm of shell fire with steadfast courage. Such adverse circumstances alone may break a man's physical strength, but cannot produce a nervous breakdown. With peace of mind a man appears to be able to stand anything; without it he cannot stand strain and responsibility of writing a letter. As long as we approach the matter from the purely biological point of view we shall continue to treat the neurotic patient by changing his environment—sending him for a sea voyage and so on. But he flies from his sickness in vain, sin he carries his fever with him. The psychologist deals with the situation more adequately by dealing with the mental conflict which makes it impossible for the patient to face his environment.

The Emergence of the Symptom.

When there is a mental conflict between two repressed complexes, the tension is relieved by the formation of a symptom which satisfies both. The purpose of every psychoneurotic symptom is to satisfy not one but both complexes. It is true that the "shell shock" man satisfies his fear complex by getting paralysed, for this gets him out of the trench as effectively as running away; but by it he also satisfies an exaggerated sense of duty which says, "a soldier never flees fear." It is not the man who admits fear, but the man who refuses to admit it who breaks down. The hysteric's pain the back satisfies not only her craving for sympathy, but gratifies her fantasy of courage which represses it, and which she receives the greater praise. A man's observationism was traced to repressed sexual curiosity on his first night in the school dormitory. But

what was it repressed? Not by a normal sense of decency, but by a moral snobbishness derived from identification of himself with the prince of pigs, Little Lord Fauntleroy. Both these elements had to be analysed and not merely the "shock" he felt.

This fact is sometimes expressed in the statement that "all neuroses are repressed desires." But we must recognize that they meet the desires of both conflicting complexes. It seems impossible that such a symptom as the fear of madness should be in any way "desired." Yet, to take one case, when this idea of madness was analysed down even such a symptom was found to satisfy two complexes. It was found to originate in an incident of 5 years of age when the patient was rushing about her bedroom naked in a frenzy of exhibitionism, and trod on a needle and screamed; her nurse came in and said, "You must be mad to rush about naked." The unconscious inference was: "If that is madness, then madness for me!" The exhibitionism was thus repressed, but persisted in an unrecognized desire to be mad, so that she might give it expression with impunity. By being mad she could satisfy her exhibitionist tendencies and rush about naked. No wonder the idea of madness unconsciously attracted her. But the symptom not only satisfied her exhibitionism, it did so in a way that was gratifying to her moral sense, for, being mad, she was exonerated from all blame and excused for her behaviour. In consciousness this repressed desire manifested itself as a phobia. Such is the nature of all phobias: they are fears of unrecognized desires in ourselves.

The Choice of Symptom.

It is of course notorious that the symptoms of the neurotic are infinite in variety, but there is a certain reason in the apparent arbitrariness of choice.

(a) *Biological reaction* may determine the suggestion. The repressed craving for sympathy finds its most natural expression in pain or sickness which, above all things, invites the pity of others, or at least in self-pity.

Vomiting is associated with the instinct of repulsion and disgust. The arousal and the repression of this instinct for other causes than the taking of noxious food produces the same physical reaction. Thus a man with chronic vomiting, unable to take even milk, found this means of giving expression to something he had done which he found revolting, and which was therefore repressed. The recollection, admission, and acceptance of the facts cured him.

(b) One cannot but be struck by the enormous number of neurotics whose symptoms started with some definite organic disease. This was brought forcibly to my mind during the war, when numbers of post-influenzal cases were sent in to the neurasthenic hospitals suffering from the "after-effects" of influenza, such as headaches, backache, fatigue, palpitation. With the exception of the heart symptom (tachycardia), I found that in almost all cases their symptoms were of a neurotic type curable by psychotherapy. It was usually found that they were cases in which the patient had undergone mental strain and conflict during the attack of influenza. For instance, one was put in what he called the "death ward" to die; several experienced air raids during their illness. When these were analysed out and the mental conflict made conscious, the symptoms of headache, backache, etc., disappeared.

Since then I have been very suspicious of the so-called "after-effects" of many medical and surgical conditions, and my suspicions have often been confirmed by successful treatment.

(c) The symptom often seems to be *accidental*, as in the case of the youth with the shaky hand. The accidental symptom is thrown into consciousness while the emotional complex is otherwise kept repressed. It is always found that there is some association between the complex and the symptom.

But whatever the symptom, it must always be one which produces a result desired by the repressed complex. This is more clearly seen in the occupational neuroses. It would be no use for a telephone girl to develop blindness as a means of escaping from a life she unconsciously loathes, but it is of great use for her to become deaf or for the cashier to get blindness or writers' cramp.

Wayway summarize the conclusions of this paper thus: Every psychoneurotic symptom is the result of endopsychic conflict between repressed complexes formed from environmental and hereditary factors during the lifetime of the individual.

III.—MENTAL STRESSES OF ADJUSTMENT IN WOMEN.

BY

JANE I. SUTTIE, M.A., M.B., Ch.B.,
Glasgow.

THE fact that mental disturbances of psychogenic origin are more frequent among women than men is always a matter of considerable interest. On the supposition that the statistics represent correctly the relative incidence of psychogenic insanity in the two sexes respectively, the inquiry suggests itself, What are the stresses peculiar to women? Without attempting an exhaustive answer, I would suggest one or two adjustments that are peculiarly difficult for women and that recur as sources of psychic disharmony with notable frequency in a great number of neurotic patients. The recognition of these particular stresses and of their significance as factors in psychic disturbances in women was gradually forced upon me on dealing with a series of adult patients, and also after observation of some girl children of varying ages. A great deal of younger material was studied in a non-professional capacity, and impressed one profoundly with the overwhelming importance of parental, familial, and pedagogic "setting" for the prophylaxis of psychopathological conditions—one had almost said, habits.

The earliest apparent difference affecting the two sexes which seems to me indicated both in psycho-analytic practice and in everyday life is the difference in the maternal attitude towards son and daughter. Parents do not even in 1922 value girl children as highly as boys, and this is largely due to the maternal attitude. Where families contain children of both sexes the girls almost invariably are aware of at least a relative disparagement that may cause any degree of feeling, from one of passive acquiescence, or of affectionate amusement, towards parents and brothers, to one of the bitterest resentment and jealousy. Western education, especially for girls, being built upon a strictly asexual convention, children do not understand the significance of the different estimation in which they are held until they have been profoundly affected and the girls usually embittered or discouraged by it. When some kind of an appreciation of sex values does dawn upon them they transfer childish jealousy and inferiority reactions to masculinity in general, while at the same time they secretly cherish a fairy prince or other fantasy that later usually—though not always—allows them to make the apparently impossible adjustment to actual marriage without too much difficulty. From these reactions, and from the much more repressive type of their upbringing, there results in girls an inferiority complex that may or may not be conscious or masked by a compensatory aggressiveness. In the writer's experience, mothers who profess themselves ardent "feminists" are equally guilty with ordinary women of this heterosexual preference for their boys. The situation is thus perpetuated from mother to children and forced by her upon the family, owing to her predominant position therein. Both sexes of course are affected by this maternal preference, but the daughters relatively much more profoundly, by reason of their longer and closer association with their mother.

In spite of this often unintentionally inculcated sense of inferiority, the exigencies of modern life demand, however, that girls shall be economically independent in competition with their contemporary males, and here there occurs a second difference between the sexes often provocative of stress to the girl. At the same time that they are expected to prepare for a career of some kind girls are also expected to acquire various domestic skills that demand at least some time and effort never demanded of the boy. This maintains or intensifies the earlier inferiority feeling by increasing the difficulties of competitive endeavour, or aggravates pre-existing resentment by affording it a seemingly rational basis. It is at this stage that resentment against the handicap of sex may be voiced as rebellion against the menstrual periods, the wearing of long hair, etc.

Throughout her education her femininity is actually a burden to the average girl, a drawback that must somehow be overcome and yet is to be exploited by other people whenever expediency demands. The strictly girlish virtues are always regarded as those of service and submission, of repression, not expression, of self; these have to be sufficiently developed, as well as an aggressiveness adequate to ensure successful economic competition with the male. Pride in girlhood and womanhood in itself as distinct from mere

frivolous coquetry or from pride in successful boyishness is the rarest feature in the upbringing of girls; it commands no economic return, and has therefore no practical value. Few girls to-day in any class but would be boys if they had the option; and whether this is based on an ultimate sex jealousy (Freud) or not, or is a reaction to the increasing economic pressure on women, it is a factor of real import for those concerned with the problems of psychic adjustments in women.

It is, moreover, just when she is reacting consciously and unconsciously to the full tide of her adolescence that the girl is also called upon to absorb herself in interests whose aim—the maintenance of herself in celibacy—is biologically her own defeat. For the average woman—and she alone concurs in—marriage and a career are self-contradictory propositions; she has therefore to contemplate life from two utterly different angles at once, and must learn to combine in practice the necessary elements of two careers without allowing either to interfere too seriously with the other. And the irony of circumstances has it that in her occupational work, with very few exceptions, the standard demanded of the woman is the man's standard. To achieve this standard, not to speak of outstripping it, the woman must always expend more effort than the man, for, as well as any other difficulty, she must always overcome at least the inertia of the interest she has suppressed. This division of interest with its inevitable associates, psychic conflict and weakening of motive, and its consequence, the need of increase of effort to reach the same standard of achievement, pursues the woman throughout her occupational career. Nor is the problem solved by those women who adopt one of the more definitely feminine careers such as domestic work, nursing, or teaching, which are more directly outlets, not so much substitutes, for their biological drives.

Under modern conditions these activities exploit, but rarely satisfy, the average woman. They offer, in exchange for her directly biologically motivated effort, a comparatively exiguous sum of money, and the bargain is considered to be adequate. Unfortunately, in these occupations the woman is of value and successful just in proportion as she identifies herself affectively with her work. Insecurity of tenure; the necessarily inadequate return for the quality of service rendered; the perpetual exasperation of repeatedly forming impermanent ties on the pattern of permanent ones; the defect of always starting afresh from the same point and never completing an experience; of always being a means for others to attain a completeness of life for ever denied themselves—all these and other similar considerations render even the more strictly feminine careers, sooner or later, as provocative of inner disharmony for women as are the more masculine.

The price of economic success, celibacy, is sometimes frankly recognized and refused, many women taking up simpler, less remunerative work because they consider it as sufficing till they can achieve their real aim, marriage; but if after all marriage is not achieved, these women are doubly victims of their biological-economic conflict, being doomed to celibacy in spite of themselves, and to a permanent economic inferiority as well.

Of course, for many women any conscious or manifest conflict of their divided interests is deferred for a varying time till the emotional tension of adolescent fantasy, which has been transferred to occupational interests, gradually evaporates and the realization of the menopause becomes defined. The psychic effect of this third stress may become appreciable at any time from the age of 30 onwards, and is not a physiologically determined condition. It is now that the quality of the individual adjustment or sublimation is put to the test. If either is sufficient the menopause will be no obstacle—in the absence of other complicating factors—to continued mental stability. If, however, there has only been a derived or an enforced enthusiasm for occupational interests, a derived or an enforced basis only, until brighter dreams should be realized, then with the fading of these dreams the inevitable clash with reality. The menopause is comes the inevitable woman's main interest and pleasure; the death of biological woman's main interest and pleasure; she has to see it approach, to meet it, in some sense, as an execution at an approximately definite date, and she has to survive it. This she can achieve in one of at least five ways: (a) Having made a suitable adjustment to reality earlier in life, she will quietly carry on; (b) she will adjust to reality before or at the menopause with more or less marked difficulty and completeness, finally making the corresponding renunciations and substitutions; (c) a certain minimum adjustment to reality will be maintained *pari passu* with a fantasy life; both kept

in watertight compartments; (d) or fantasy may be reinforced to the extent of the denial of reality and become definitely psychotic; (e) or, as Freud suggests, there may be a regression to a pregenital—that is, anal-erotic—stage of the libido, producing the characteristic changes in the personality.

Except in the first instance, the psychic conflict attending climacteric adjustment is never negligible, and is usually more or less severe and prolonged. It is also an adjustment that most men escape, and constitutes a third stress peculiar to women. This stress, as I have indicated, is often felt considerably before the actual physiological onset of the climacteric, but the association is too direct to suggest any other classification. For many the idea of the menopause has something of the foretaste of death, of a prevision of personal dissolution, and demands an adjustment profoundly painful to the ego feeling, even for some married women, while for celibates it has the additional poignancy of depriving them for ever of an unopened chapter of life of which they feel themselves to have been cheated. Here, too, there is apparent again the sense of sex injustice against women, because sex experience without social or other consequences is always conceivably possible for celibate men, but not for women.

Again, modern cultural needs and standards also range themselves with her economic necessity against the fulfilment of woman's biological ends, increasing and complicating her conflicts both in celibate and in married life. Her own cultural needs as well as economic pressure help to forbid or defer marriage or to lower the birth rate. With the expansion of their cultural interests, women are becoming increasingly unwilling to be submerged for ten to fifteen years in the crushing drudgery of rearing a large family; yet instinctive needs cannot be entirely suppressed, so that many women are doomed to be at war with themselves to some extent, however they are situated. For the married as for the celibate it is a constant conflict, variously stressed, of economic pressure and cultural needs as against biological ends. And here again the heavier stress at least falls upon the woman, in so much as her more urgent reproductive instinct is also thwarted.

Women therefore are divided between their biological needs and economic necessity and also between the former and their cultural requirements. They are burdened as well with a sex inferiority implanted in them in the home, and thoroughly bitten in by the mordant of an education that tacitly implies that women must be as nearly men as possible to be of any economic value, and few women in the twentieth century dare not have an economic value. Many women equal masculine achievement, but at a price that the majority of their sex can never pay. Racially these exceptional women are not significant, they are too infertile to affect the numbers of the average woman, who is the really important person—the mother who bequeaths both her biological drive and therefore also her problems of adjustment to the succeeding generation.

Modern social conditions are compelling women more and more to model themselves on men, which, except in rare cases, inevitably causes intrapsychic conflict and division of interest. This conflict is increased and complicated by the growing cultural needs and ideals of both sexes. The idea of masculine superiority is maintained largely by women by their preference for their sons, and is further strengthened by the standard of occupational and cultural achievement being as yet always the masculine one. It is impossible to despise what is one's avowed goal. The present prevalent ideal of life for both sexes and in all classes is in fact modelled on that of the active untrammelled male who is free to go his way, in full—but infertile—satisfaction, without giving hostages to fortune as he goes. So much so is this the case that there are already indications of an increasing intrasexual conflict as between married and celibate in both sexes respectively. It is needless to restate the corresponding intrapsychic conflict this evokes in the woman or to point out how directly it is related to the general social unrest and discontent.

Women are suffering from a growing deviation of interest from biological objectives forced upon them by the conditions of twentieth-century life. This seems to affect them more than it does men, probably because women's biological objectives are more intrinsically of the web and woof of their lives—that is, are reproductive and cultural, not merely sexual, and constitute life itself, not merely incidents in that life. Successful sublimation of biological interests, therefore, is a much more difficult and far rarer thing in women than in men, largely because of the difference in type between male and female sexuality. This is probably the real reason why men still lead the world in science, art, literature, etc.:

women being always handicapped in the struggle for supreme success by their lack of singleness of purpose as compared with men, and this handicap is perhaps the guarantee for racial survival.

There can be no simple and universal solution of these women's problems, but their prevalence and complexity call for attention. Industrialism cannot just be wiped out; biological needs cannot be allowed to run riot; restraint, discipline, effort, must be encouraged in both sexes—civilization is based on these. Neither sex can have every advantage, but although the lesser adaptability of women seems inevitable, and even apparently biologically desirable, the recognition of the causes of this fact is absolutely essential in psychiatry and pedagogy, and ought to be known to the woman herself and should not be misunderstood as an inferiority. It seems to me that the only alternative solutions of the woman's question so-called are either the abandonment of the present economic system or an adequate grasp of the question at issue by all concerned, with a view to a more rational training of the young in their ideas of sex values. It is not a matter of the relative superiority of either sex, but of self-knowledge and mutual respect for both.

The particular stresses discussed are of course merely indications of how women of to-day are affected by the unceasing conflict between sex and society on which civilization is precariously poised. But, such as they are, the type and the constant recurrence of these stresses afford food for thought if it is remembered that civilization after civilization has waxed to some such height of female emancipation as we enjoy to-day and then collapsed. No one, of course, and certainly no woman, would venture to say the decline was always *propter* rather than *post hoc*, but the chronological relationship remains and is significant. Any social system or standard of civilization that bears too hardly on the biological needs of either or both sexes is of course doomed. Indications such as I have sketched would suggest that women at least are in some ways overtaken by our social system to-day and that once more it may be a question of civilization versus race. Although, however, so much of the solution of these difficulties must be sociological, their significance for the individual is of the highest interest to the psychiatrist, who, being cognizant at first hand of their prevalence and importance as morbid agents, must therefore play a large part in their elucidation and control.

IV.—THE PSYCHIC AND ENDOCRINE FACTORS IN FUNCTIONAL DISORDERS.

BY
H. CRICHTON MILLER, M.A., M.D.,
London.

I must begin with a word of explanation about the phrase "functional disorders." I use it, not in a strictly scientific sense, but as the most convenient label for a group of conditions in which no structural alteration, appreciable by our present methods of investigation, has any etiological significance. The advance of science has already transferred a number of morbid conditions from the functional to the organic group. Only a few years ago, for instance, paralysis agitans was regarded as functional. To-day, it is generally attributed to a definite and localized degeneration.

I note that in another Section the subject of binocular vision is to be discussed. I might have given that phrase as an alternative title for my own paper. It is my object to stimulate you to "use your lazy eye"; whether the prism is needed on the right or the left is a matter for each one to settle for himself; but I venture to say of the profession in general that when we contemplate these functional conditions very few of us are without bias—be it towards the somatic or the psychic. And if we have a "lazy eye," we cannot have binocular vision; and where there is not binocular vision there cannot be a stereoscopic image. In the nuderworld of psychoanalysis the "complex" and the "complex-stimulator" are familiar phrases. There are some physicians to whom a psychic theory of a neurosis acts as a vigorous complex-stimulator, and there are physicians who have been analysed *a outrance*, who yet seem to have an unresolved complex about the influence of the organism on thought and behaviour. One would almost think, to hear the defensive fervour of some of these partisan scientists, that they have some personal stake in proving an exclusively organic or, it may be, an exclusively psychic etiology for a given clinical state.

Let us try, then, to approach the subject with that freedom from prejudice which is always preached by psychoanalysts

and sometimes practised by scientists. But if we are to rid our minds of prejudice we must do what we can to free them of ignorance, and that means that we should study as we can the side we happen to know least about. Now this is not an easy task. On the psychic side the literature is vast. Psychotherapy seems to abolish literary inhibition on those of us who practise it. And the endocrinologists appear to be following this evil example. The reports of Vienna are well-nigh matched by the records of endocrine therapy claimed by New York; and plain doctors like ourselves find it hard to keep their sense of proportion. One would wish that our country could stand in this matter for that dispassionate spirit of compromise which is, at the same time, the scientific spirit of correlation.

But the scientific spirit finds itself confronted with serious difficulties on either hand. The psychic factor, despite the bold claims of the Freudians, eludes scientific treatment beyond a certain point. Nor is this due entirely to our present ignorance, for it will always elude such treatment. Life, ladies and gentlemen, is primarily an art; and the sooner the scientific psychologist recognizes his limitations the less likely will he be to expose himself to criticism. Freud may be, and I believe is, fundamentally correct; Jung may illumine us still further; but the last word will always come from a Robert Louis Stevenson.

And on the endocrine side, what do we find? Certain very exact data about the production of rickets in guinea-pigs, a good deal of well-attested information on the mental results of thyroid feeding in cretins, and beyond that a mass of probabilities and possibilities. We cannot complain of this. It is largely inherent in the nature of the subject, for up till now the methods of exact science have been not a little baffled in the search after endocrine truth. The x rays have enabled us to gauge with some show of objective accuracy the size of the pituitary; the estimate of the basal metabolic rate bears a striking correlation to thyroid activity; and the results of surgical interference with gonads or thyroid can be noted. But even this last method is shorn of its exactitude when we consider that the removal of a portion of thyroid may or may not implicate some of the parathyroid bodies, and, seeing that we are not even positive as to the number of these bodies, the validity of our conclusions is still further compromised.

From all this it must be evident that we are groping in a sphere where facts are peculiarly elusive, where opinions are necessarily conflicting, where speculation is justifiable and empiricism imperative. And even in our empiricism we are hampered, for the simple reason that we are in the hands of the commercial drug houses. I took the trouble not long ago to inquire of several well-known firms whether their respective preparations of thyroid contained or did not contain the parathyroid constituent. The replies were depressing. A firm whose accuracy I have reason to trust explained that owing to the variation in the position of the parathyroid there was always liable to be a slight amount present in thyroid preparations. They had only succeeded in isolating parathyroid in very small quantities and at great expense.

Another firm confessed to the same uncertainty, and expressed scepticism as to the possibility of detecting and separating the parathyroid from the thyroid. A well-known American firm reported that they had only found one man in the United States who was able to locate the parathyroid and extract it for use. The accumulation of detailed evidence in this direction made one inclined to discount as mere commercial rhetoric the unqualified statements of other firms that their thyroid or parathyroid tablets were prepared in each case from the gland, the whole gland, and nothing but the gland.

Thus our clinical empiricism is hampered by potential fallacy at the very outset, for it is obvious that when our clinical results from the use of a certain hormone contradict those obtained by others there may be a possible explanation in the relative value of the preparations used.

These considerations, and others that I have not mentioned, make it specially difficult to formulate definite and demonstrable views on this subject. But apart from the strictly scientific study of these problems, there is a mass of facts supported by universal human experience that we cannot afford to ignore. First of all, there is the correlation between physiognomy and mentality—a correlation which provides the cartoonist with a language of his own. Let us suppose that in a play a somewhat invertebrate creature and an American "captain of industry" appear; what would we say

the first were broad-shouldered, square-jawed, with black hair and deep-set eyes, while the latter appeared slender, fair, thinness, and frog-eyed? We would protest at the incongruity; and in our protest we would implicitly admit that the adrenal type of humanity is rarely submissive or effeminate, and the thymocentric is never endowed with initiative, determination, and perseverance.

But long before there were captives of industry or pale young curators mauling had practised on a large scale an experiment in the influence of the gonads on the mentality of the horse. Admittedly the operation of castration alters the behaviour-reactions of the horse very greatly. The psychology of the stallion is a totally different thing from that of the gelding. Man castrates the horse to promote his docility in the presence of such stimuli as steam rollers, field artillery, and lilies. He knows that the withdrawal of the gonad hormone constitutes a condition that transforms the reflex of behaviour. Man has known all this for centuries about the horse: it is only dawning on him to-day that the analogy holds in his own case.

We see two boys, sons of the same parents, brought up in the same environment. The one is tough, daring, high-spirited, and early develops a proclivity for the society of the opposite sex. The other is flabby, lethargic, pusillanimous, and morbidly shy in the presence of women. We ponder on the contrast, and it never occurs to us that a clue might be found in that attack of mumps that the second boy had, when he was 12, with a few days' orchitis that was soon forgotten. In other words, the unknown virus of parotitis infectiva, with its specific selection of gonad tissue, is the counterpart of the veterinary surgeon's knife. But when we have described these two types, and correlated them with an important endocrine contrast, we have not said the last word. There are certain moral qualities that may yet transcend the trend of behaviour: the first, full of animal courage, may be a moral coward and make shipwreck of his life; the second may be a moral hero, and overcome his numerous limitations and make good in the completest sense of the word. In short, the endocrine balance in man may condition, but it does not determine behaviour.

Take another example. McCarrison, in his great book on the thyroid, has shown that in the causation of exophthalmic goitre three factors play a part—the nutritional, the toxic, and the psychic. How many cases of exophthalmic goitre to-day are being treated from these different standpoints? I venture to think, very few. One falls into the hands of the organic scientist, who treats the patient by organic methods, and for the rest bids her to cease from worrying. Another falls into the hands of the psycho-analyst—the kind that wears blinkers—and he proceeds *secundum artem* to lay bare a mother-fixation, while he ignores the physical factors entirely. Nevertheless, it must be obvious to all open-minded observers that both lines of treatment are called for, not necessarily concurrently, but each in its place.

An example such as this throws light on an old shibboleth—"What mind can cause, mind can cure." At one time I firmly believed in that generalization; now I make my reservations. I believe that the emotional shock which so frequently precipitates the attack of exophthalmic goitre constitutes only one condition of the onset, the other being of a physical character. That shock sets in motion a chain of physiological disturbance which cannot be redressed merely by the adjustment of emotional disequilibrium, though it may well be true that the physiological disturbance can never be completely set right until the emotional factor has been successfully dealt with. We should therefore make a point, in dealing with all functional conditions, of assessing to the best of our ability three factors:

1. *Inherited endocrine pattern.* This involves some investigation of the patient's family history, not only from the psychic point of view, but also from the physical. "My father was a musician. He was a very tall striking person." This would suggest the pituitary heredity from both mental and physical evidence. "My mother was dark and thin, and a martyr to asthma" would similarly suggest an adrenal overemphasis on the maternal side. The more we know the more numerous are the sources from which we can draw information of a potentially fruitful order.

2. *Personal endocrine history.* In general we want to know how the endocrine system has reacted to the physiological crises of puberty, marriage, pregnancy, etc., and also how it may have been influenced by pathological factors. For instance, a late puberty may confirm the impression that we are dealing with a thymocentric type; the beneficial effects of

pregnancy may suggest a hyperthyroid woman; and soon. But much more important as a rule is the history of disease; the chronic colds and sore throats with several attacks of tonsillitis that culminated in a belated enucleation of tonsils and removal of adenoids; then the laryngologist's comforting assurance, "Now the patient will feel better than he has ever felt." How often does a laryngologist in such circumstances stop to think of the once efficient thyroid now morphologically altered beyond repair, that will never again do a full day's work? Or the case of chronic constipation with its disastrous adrenal implications—how often does the cure of the symptom leave behind an irremediable hypoadrenia and a vagotonia that will influence mind and body alike till death?

3. *The patient's emotional development.* This—the psychic—side of the picture is to me neither more nor less important than the somatic. We can only reach a just estimate of the etiological factors if we inquire into both sides of the picture with some minuteness. Prejudiced—native and acquired—generally prompts a disproportionate interest in the one side and a corresponding lack or absence of interest in the other. This is the real secret of our failure in handling functional cases. One man will hardly deign to count a pulse, while another fails to elicit the story of an unrequited love. For my own part I think there is little to choose in probable etiologic importance between a dental abscess and a step-mother. They both have a way of assuming pathogenic importance unobserved. The one eludes the dentist's observation, the other the patient's.

I have tried to show that the interdependence of endocrine and psychic factors in general confronts us at every turn. Let us now see whether any specific correlation between individual glands and mental characteristics can be traced. And here we pass still farther from the objective to the speculative.

Let us begin with the thyroid. Leonard Williams, more than anyone else, I think, has emphasized the feminine function of this gland. As it is the great gland of anabolism, so it must be of greater significance to the female on whom katabolic demands are so unequal and at times so excessive. But I think there is a broader view possible. I would submit that the thyroid is the gland of creation. Its importance from the procreative point of view is commensurate with the respective shares of the male and female in reproduction. But in the wider sense of creation, as artistic creation, the thyroid still seems the dominant factor. Surely we will all admit that the creative artist who becomes subthyroidic ceases to create? Some years ago, in a paper on a kindred subject, I asked if anyone had ever heard of a myxoedematous artist. The only reply came from Dr. Tredgold, who cited the case of a croftin who had lived in Zürich in the eighteenth century, and was an artist of some repute. Once more I ask for cases of subthyroidic creators—be it of works of art or of children. True, the subthyroidic woman is not necessarily sterile, but I notice among my gynaecological friends a tendency to prescribe thyroid extract as a routine treatment for sterility. Again, I would have you observe the mutual exclusiveness of child-bearing and artistic creation. Had I time I could cite several cases that in my opinion go a long way to show that the woman of artistic ability ceases to create to show that the woman of largely or altogether, as soon as she is taken up with the maternal function—and this not for any superficial reason of time and opportunity, but because her storehouse of creative energy is unable to cope with both kinds of creation. The psychotherapist is frequently called upon to cope with the artist whose capacity for expression has deserted him or her. In such cases I believe we should always study very carefully the state of the thyroid function, in addition to the emotional factors. These latter appear to me frequently to be secondary to the failure of self-expression, rather than primary and causative.

If we now turn to the pituitary, we are at once confronted by the enigma of its own paradox. The mutually inhibiting actions of thyroid and parathyroid, or adrenal cortex and adrenal medulla, are relatively simple problems as compared with those of the anterior and posterior pituitaries. Borman with those of the anterior (only he does not enunciate it makes the ingenious suggestion) that the postpituitary is responsible merely as a suggestion) that the postpituitary is responsible for differentiation of sexual types. Postpituitary failure, therefore, makes for sexual characteristic pituitary it is more male is an essential Fröhlich's syndrome. Now the psychic mould of a case

Of the anterior failure in the sole cause, of

of Fröhlich's syndrome is full of interest, and, if I may judge from my slight experience, fairly constant. We have a large fat man, morbidly juvenile in appearance, with undersized genitalia, and little or no sexual desire. He has a strong sense of inferiority from his "deprivation complex," with the compensatory self-assertion that goes with that inferiority. On the other hand, the man with a well-developed anterior pituitary tends to be tall, spare, and normal in sexual characteristics. But the psychic correlative of well-developed masculinity is power, and some element of power in character make-up is undoubtedly attributable to the pituitary factor. There is another psychic factor that we have good grounds for associating with this gland, and that is imagination.

Now the adrenals are also sources of power, in that they control the sympathetic system, and thereby dominate the fight and flight reactions. But the power quality of the adrenal-centred type is of the objective order and depends on immediate stimulation. I therefore venture to suggest that the power coefficient of any given individual is made up of the combined pituitary and adrenal hormones and varies in type according to which of these two hormones predominates. Thus the pituitary-centred provides the type with the power fantasy, while the adrenal-centred provides that with the power energy. Our Napoleons, Bottomleys, and Northcliffs are presumably pituitary-centred, while the classical type of British naval officer can confidently be classed as adrenal-centred.

I have now suggested a speculative and rough classification of these three hormones—thyroid for creation, pituitary for subjective power, and adrenal for objective power. I have not done so with any particular desire to convince you of my views. My intention has rather been to show you how some such hypothesis can be usefully associated with our psychological conceptions.

It has long seemed to me that the Freudian theory suffers from an ambiguity at the outset in its presentation of the human dynamic. The *libido* is referred to as if it were homogeneous. This is only so far as I understand the Freudian theory of to-day. One criticizes with diffidence, as the stock reply of Freudians to their critics is to point out that the critic's comprehension is limited or his information out of date. It seems to me that Adler's contribution on power psychology needs re-emphasis. I would submit that the personal dynamic of any human being consists of three main urges: (a) the creative urge, (b) the ideal-power urge, (c) the real-power urge—the three corresponding to the three hormones previously referred to.

Now from these three main urges we can build the scaffolding at any rate of a sex psychology. Motherhood is not likely to act as a strong incentive to the non-creative woman. The marital state cannot be expected to attract a woman with a strong power fantasy, in that the condition of self-surrender is implicit. Nor can it attract the man who is predominantly artistic or creative, and exceptionally ill equipped on the power side; for the man with a submissive psychology makes a useless husband outside musical comedy.

Regarded from this point of view the problem of homosexuality becomes to some extent simplified. We are told by the Freudians that the average adult is only a man or a woman to the extent of 75 per cent.; the rest is called a homosexual component. Supposing this observation to be correct, could we not restate it thus: The complete man is power-inspired, with a very small residue of creative impulse; the average man has a weaker power urge and a somewhat stronger creative impulse. The complete woman is all creative with none of the power factor that obstructs submission. Perhaps it is fortunate for society that these extreme types are not more common.

Now, if we take a family in which the emotional background is such as to favour the production of a homosexual son—the mother fixation, the father fear, and so on—we are justified in surmising that the sons with the strongest power psychology will win through to a normal adult orientation, while the one with the largest creative component will succumb to the warping emotional forces, and end up as the homosexual. *Per contra*, the daughter with the strongest power psychology will fail to make her adjustment to the potential mate, simply because the conception of surrender has become impossible to her, in the atmosphere created by a bullying father. We see, therefore, that the endocrine pattern of the child has a good deal to say to the developmental reactions of the adolescent and the ultimate sex orientation of the adult.

As an illustration I quote the following case:

A girl of 14½, who was alleged to be unmanageable both at home and at school, untruthful, and given to petty acts of theft. On the psychological side we had a complete rebel and exhibitionist psychology, with a power urge that seemed incapable of sublimation. Her father was a cunning tyrant and a cowardly bully. He had divorced her mother. She hated her father personally, and her school teachers *ex officio*. She derived the greatest pleasure of her life from outwitting them. She was slack and careless in games as in everything else, though she had mental ability above the average. She would secretly pawn an article of clothing, and then, for want of a better way of spending the proceeds, would take a taxi from school to her home. She was an inveterate sensation-monger, and preferred to be the centre of a dramatic school upheaval than to be ignored as a mediocrity. She was alleged to be devoted to pets, but when she had pets she was found to be secretly cruel to them, and on occasions would even kill them off, and then affect regret. Thus the outline of the psychological picture was fairly complete.

Now let us turn to the physical side. She was very powerfully built, and had precocious sexual development. She was not unshapely in the sense that the subthyroidic is unshapely. She had a slow pulse. She was troubled with enuresis diurna, which was of course put down to "naughtiness," "mere carelessness," etc. I believe this patient belonged to a type that provides many young delinquent girls. The thyroid function was manifestly subnormal. I imagine that the pituitary was overactive. Thus we had a notable absence of the maternal urge of the normal adolescent girl, depending on her deficient creative impulse. Hence the instinct to protect helpless creatures, which is normally the basis of a girl's interest in pets, gave way to a sadistic tendency. The pituitary overaction caused her to live in a fantasy world of power, a world in which she performed wild tomboy feats of the most extravagant description. It caused her to plot and contrive schemes whereby she would make her elders dance to the tune she piped. Finally, it may reasonably be supposed that some connexion existed between the pituitary condition and the enuresis. At the same time it must be remembered that on the adrenal side she was obviously defective. All the objective energy of the really fighting rebel was notably absent. Her endurance was from every point of view below par, and she was only saved by her pituitary from a vagotonic state of inertia.

Now the picture I have tried to fill in is one of essential and perhaps lifelong conflict. It is the picture of an adolescent whose endocrine equipment does not lead to mating or parenthood. No girl with a subjective power urge of such dimensions can contemplate the rôle of the wife with contentment, nor can one so devoid of creative potentiality feel any attraction in the possibility of motherhood. Hence repressions of the most devastating kind begin to occur at an early age; for repression is the natural method of reconciling elements that are irreconcilable in consciousness. Our instinctive equipment is based upon our endocrine pattern. When it can be reconciled with our destiny things tend to go well with us. If it is irreconcilable with our destiny, complexes inevitably result. And our biological destiny, whatever may be our ultimate fate, is parenthood. To say that many women are perfectly happy as spinsters, and that many men prefer to be celibates, is in general an admission of an endocrine failure which unfits them for parenthood. But whether or not the adjustment to celibacy be satisfactory only the analyst can tell; and for my part the more experience I have of analysis the more convinced I am that—welcome or unwelcome—our biological destiny haunts us from childhood to the climacteric.

The same correlation between endocrine make-up and psychological conflict is illustrated in a much commoner group of cases—the anxiety states. The war has made us all painfully familiar with these cases, but even in times of actual peace such as we had before 1914, and of nominal peace such as we have had since the armistice, they are very frequent. On the psychological side they consist in conflict which has resulted in complexes with a strong fear affect. I imagine that all fear can be traced back to one of two sources: either it is the fear of extinction, including all the religious fears of eternal punishment, or it is a mating fear—in the male the haunting fear of impotence (which is infinitely commoner than most of us believe), and in the female the fear of male aggression in the sexual act. From these two springs arise the protean phobias of the anxiety states, and in no department of functional disorder has analytical treatment more completely justified itself.

But what in general is the somatic side of the condition? Does it not correspond unmistakably with the condition known as sympathetotonia—thin, tense, high complexion, overactive sweat function, irritable or irregular peristalsis, rapid pulse, and so on? In other words, we learn to correlate a fear complex with hyperadrenia, or a repressed fear with a constantly stimulated fight or flight mechanism. If this much be granted, it is obvious that the individual's endocrine

pattern must to a great extent condition the effects of a fear repression. The individual with a balanced adrenal function will be less likely than one of the opposite type to develop the typical anxiety neurosis. On the other hand, his repressed fear is more likely to manifest itself in hysterical defences. But once again I must emphasize the fact that the endocrine pattern only conditions and does not determine the ultimate reaction. We shall fall into serious error if we imagine that the endocrine factor is the final determinant of behaviour.

As a last illustration of the interdependence of the endocrine and emotional factors, I would mention dementia praecox; let us take the paranoid type in particular. On the psychic side we have a history, it may be, of a bright boy who has done well at school and begun to flag, perhaps, at about seventeen. (The cases in which an element of mental defect can be established need not be considered for the moment.) Then, as the adolescent faces manhood, he begins to regress, and the picture which Jung has given us is slowly elaborated. It is a picture of generalized retreat from the challenge of life; a regression from maturity to the cradle; an ever-increasing tendency to rationalize his failures into the inevitable outcome of circumstance and environment. And in every case, without exception, we can trace how life was presented as too exacting and too menacing, while the nirvana state of protection in a maternal environment became correspondingly too seductive.

And now turn to the other side of the picture. Mott has established a striking correlation between dementia praecox and aspermatogenesis. I do not suggest that this is the outcome of the emotional regression, but I do submit that it is reasonable to regard it as the conditioning factor. To argue the claims of the one theory against the other is to me utterly unscientific. If a motor car steps on a hill, it is useless to argue as to whether the hill is too steep or the engine too weak. The plain fact is that the engine is too weak for that particular hill. We know—at least analysts know—that in practically every case of dementia praecox life's challenge has been made steeper than it need be. It is not surprising, then, that the cases of failure are those with an inadequate biological dynamic. And in the male it is this inadequate dynamic, based upon a low endocrine efficiency, that produces that train of psychological retreats that we call dementia praecox. Once more we see the emotional conflict conditioned by the incompatibility between the individual's instinctive equipment and his destiny. To every case of dementia praecox his destiny has appeared unattainable, and the thought of that destiny—mainly biological, but social as well—has haunted him from reality into a state of ineffective fantasy.

In conclusion, allow me to say once again that this paper is frankly speculative and makes no claim to scientifically demonstrable accuracy. I make no apology for this, as I have already indicated the difficulties which at present stand in the way of a strictly scientific handling either of the psychic or of the endocrine side of the material with which we are dealing.

The immediate hope of progress in this field seems to me to depend on the advance of individual clinical observation of the apparent correlations between psychic and endocrine factors and the criticism and comparison of the hypothetical conclusions that can be drawn. In this work we may expect to be denied the consolation of obtaining scientifically demonstrable results; but we may at least aim at securing the first condition of accurate observation and true theory—namely, that freedom from bias which alone gives binocular vision.

V.—PSYCHOTHERAPY WITH SPECIAL REFERENCE TO AUTO-SUGGESTION.

BY

CHARLES F. HARFORD, M.A., M.D.,
London.

PSYCHOTHERAPY, if it is to gain general recognition and wide adoption, must be based on a sound psychology. The differences of technique which are advocated by the pioneers in the various systems which are in vogue seem to suggest to some that there is no true science of the mind. While therefore we do well to practise those methods which commend themselves to us, and which have proved useful in our hands, and to advocate the same, yet we must seek to establish a common basis of psychology which must be the foundation of every system.

The late Dr. Rivers, in a lecture on "Mind and Medicine," has claimed that determinism in the psychical sphere is as important as in the physical sphere, and, without surrendering our belief in the agency of free-will, we shall all do well to follow this advice as a working hypothesis.

There are three great principles which seem to me to be common to all systems of psychotherapy however much they may vary in their application. They are as follows:

1. A recognition of the meaning and paramount influence of the unconscious mind in the human economy, using the term from the widest standpoint.
2. The adoption of certain methods through which the "unconscious" can be influenced.
3. The final application of these methods by the individual concerned.

These great principles govern the methods of auto-suggestion associated with the name of M. Coué, and I propose to indicate how these are carried out.

The Unconscious Mind.

1. The unconscious mind finds its counterpart in the system of Coué in the "imagination." It is obvious that this cannot be regarded as a complete definition of the term "the unconscious," but for practical purposes the expression is of great value in presenting to our patients the idea of "the unconscious" which it is important that they should realize. Imagination is used more in the sense of imaging than imagining, as this word commonly signifies, and it represents the view that every action, mental or physical, of the human personality is preceded by the image or picture of what is about to happen. The imagination of the artist or poet is an instance of this, which is in accordance with our common phraseology.

This imaging is something which is charged with force and consequently with emotion, so that it becomes irresistible. I have referred to this in a previous paper as "the vital force within us which never sleeps night or day, which is not only the source of our wide-awake thoughts, or of our nightly dreams, but which is the supreme controller of all our bodily functions." Interpreted in detail, this means that it is the same mind control which directs the action of the circulatory and digestive systems, which is responsible for what are usually spoken of as our voluntary movements, and, on the other hand, directs the processes of repair when any part of the human organism is deranged. It is the same mind control which is responsible for our thoughts and emotions, and this is the conception which we have of this use of the word "imagination."

This, as we have said, represents in some measure at least the idea of the "unconscious," and it is essential that we should understand that this great process is going on apart from consciousness and that we are only aware of the results of this imagination.

Another fundamental principle of this system of mind control is that, in its relation to our bodily functions at least, it is designed for the perfect adaptation of every part, and that it is only when this is deranged that irregularities occur. With this idea before us it is our great aim to secure that the imagination may carry out its great task unhindered either by past or present adverse influences.

Suggestion.

2. We now pass to consider one of the methods by which the "imagination" can be influenced whether for good or ill, and that is by suggestion, and particularly by that variety which we speak of as auto-suggestion. M. Coué illustrates this process by the common hypothesis that we have in effect two selves—a conscious self and an unconscious self. Of the latter we have already spoken, and it would almost appear as if there was no room left for any conscious direction. This is very far from being the case, and M. Coué describes his system as self-mastery by auto-suggestion.

The truth is that we have not only the power but the responsibility of controlling our personality. If, however, this is to be done the conscious must act through the unconscious by the process of auto-suggestion. This, however, must be practised with good judgement, for, as I often say to my patients, "Your imagination will not be bullied by me or even by you." This explains many of our past failures. We have tried to change our own habits and those of others by a *tour de force*, and the very violence of our efforts has produced the contrary effect. This phenomenon has been spoken of by Coué and Baudouin as the law of reversed effort,

and although this description has been criticized it has been of practical usefulness to many.

Auto-Suggestion.

3. If it is admitted that each individual must apply the psychological remedy to his own case, however much he may be helped by another to make his adjustment, this process becomes essentially one of auto-suggestion. In the system of Coué the greatest stress is laid upon this factor, and though there must be the element of suggestion in every case, yet each individual is shown that the power to obtain relief rests with him and him alone. I often say to my patients, "You are the master of your own ship."

Dr. Mouier-Williams has established a small free clinic for testing Coué's system of collective auto-suggestion in which I am assisting him. In this clinic and in my ophthalmological practice, and also in the treatment of malarial and dysenteric pensioners, I am testing this technique of auto-suggestion, concerning which it is hoped later on to publish some of our results.

DISCUSSION.

Dr. R. G. GORDON (Bath) said there had not been much advance in psychotherapeutics during the last two years. Psychology and biology were not antagonistic, and all psychoneurosis was not due to sexual influences. The unit of any process corresponded to a reflex arc set in motion by a stimulus which might be a mental or biochemical change, and it was on these lines that psychopathology should be built up. Psychotherapists must work on a wide basis of physiology as a whole if progress was to be made.

Dr. MURRAY LYON (Edinburgh) said that hypnotism had been largely abandoned and suggestion was the main means of all treatment in one form or another: there was nothing new in what Coué said. Syphilitic neurotics were all potential tabetics or general paresics, but by suitable treatment the development of these diseases should be prevented. Insomnia, lightning pains, and ataxia of tabes had been controlled by suggestion.

Dr. CONSELL (Edinburgh) agreed with Dr. Hadfield that every symptom was due to endopsychic conflict—sexual instinct was almost invariably involved as one factor. The environmental factor was of great importance.

Dr. WILLIAM CALWELL (Belfast) objected to the age of 3 years as being that of the awakening of consciousness; this was a gradual process, a process of evolution, a gradual unfolding, not an isolated fact. He urged that pre-natal forces and those acting during the first two years must not be lost sight of. There was too much insulation by the psyche; psychology was the physiology of the higher centres, but the examination was held from a different aspect. Heredity was a much stronger force than Dr. Hadfield said; physical characters were inherited, and so were mannerisms and moral and immoral tendencies. Dr. Crichton Miller's endocrine organ influence could be amplified; the tone of muscles had an effect on the mental attitude. Perhaps the stimulation of a cold bath and a rough towelling of the skin had more than a reflex action; perhaps it stimulated an internal secretion from those organs.

Dr. HELEN BOYLE (Brighton) thought Dr. Suttie had been unduly pessimistic about the outlook for women. Temperament played a very important part—"Give the child a start with no feeling of inferiority to her brothers, praise her for what she is good at, and she will do whatever she has to attempt well." Girls must know their limitation, whether submissive or aggressive; there was plenty of room in the world for all sorts.

Resolution by the Section.

The PRESIDENT (Professor George M. Robertson) moved the following motion, which was carried unanimously:

"The members of the Section of Neurology and Psychological-Medicine of the British Medical Association are of opinion that instruction in psychology and psychopathology (medical psychology) should form part of the curriculum of all medical students, and further, that this opinion should be brought to the notice of the General Medical Council and all the teaching bodies in the United Kingdom and Ireland."

SECTION OF RADIOLOGY AND ELECTROLOGY.

LEONARD A. ROWDEN, M.B., C.M., President.

DISCUSSION ON THE THERAPEUTIC VALUE OF STATIC ELECTRICITY AND HIGH-FREQUENCY CURRENTS.

OPENING PAPERS.

1.—STATIC CURRENTS.

BY

F. HOWARD HUMPHRIS, M.D. BRUX., F.R.C.P. EDIN.,

D.M.R. and E. Cantab.,

Late Officer-in-Charge, X-ray and Electrotherapeutic Departments, 3rd London General Hospital.

THE THERAPEUTIC history is full of the stories of various agents which come heralded with much noise and advertisement, and have a sensational rocket-like rise; then suddenly their light goes out and they are forgotten. This cannot be said of static electricity. It has been described as Nature's safest and most rational remedy.

Discovered about 1672 by Otto von Guericke, it cannot for many years be traced; but in 1750 Jallabert, Professor in Experimental Philosophy in Geneva, published a book in twelve chapters, *Experimenta electrica visibus medicis applicata*, in which the successful treatment of diseases of the muscular and nervous systems by means of static electricity is described. Thus it was used as a therapeutic agent prior to 1750, and it has withstood the test of time since then.

The therapeutic advantages and the wide range of utility of static currents are now generally admitted by all those who have thoroughly examined their merits. This change is of comparatively modern date, having been brought about within the last twenty or twenty-five years, and is due chiefly to the work of the late Professor William James Morton and Dr. Snow in New York.

In order to have a clear conception of the therapeutic value of static electricity it is necessary to describe the different forms or modalities which are obtainable from the static machine. The word "modality" is disliked by several authorities; but I plead for its inclusion as being the one least open to objection.

Although one frequently has to do so owing to greater familiarity with the term, it is an anachronism to speak of static currents, for when a static charge becomes a current it is no longer static. Nearly twenty years ago I published in the *Lancet* a chart of static modalities, and though then, and since then, several objections have been taken to the word, no better has been suggested.

There may be said to be six chief modalities obtainable for therapeutic purposes. Where the more suitable apparatus is not available, x-ray tubes may be excited, and D'Arsonval, Tesla, and Oudin currents may be derived from the static machine; but these are not included in this paper to-day.

The six forms which are here briefly outlined are:

1. The static bath, also known as static charge, static insulation, or general electrification.
2. The static wave current.
3. The static induced current.
4. The brush discharge.
5. The static spark.
6. The high-potential vacuum.

1. The Static Bath.

Here the patient comfortably reclines on a chair, placed upon an insulated platform connected to the negative side of the machine, and is untouched by any electrode and untroubled by any necessity for the removal of clothing, unless he or she is conscious of any metallic braid, hairpins, etc. Relaxed and comfortable, the operator or friends well away from the platform, the machine is started, and the patient should experience little except a feeling as of a gentle breeze passing all round him; but there is nothing alarming even to the most nervous patient. His sensations are quite pleasant. Such is its administration—the simplest and most soothing of all forms of static electricity. It is not as efficient as some others, nor are its therapeutic effects so marked, and the indications for it do not cover a very wide range; but where a constitutional sedative is required to the otherwise healthy but generally tired-out individual, or to a nervous or highly

strung patient, its effects are excellent, the patient often falling into a gentle sleep during its administration and awakening much refreshed and soothed.

As to the manner in which the current produces its effects it is difficult to speak. Experiments have been made which give negative results as to any demonstrable physiological action; but to anyone who has used this current properly it is evident that in some definite way the effects are produced, and with some diffidence I suggest the following hypothesis.

It is known that any uninterrupted static current has a tendency to flow over and remain on the surface of the charged body. When one considers that this current of very high voltage, but of minute milliamperage, is flowing continuously over the delicate nerve endings in the skin of the whole body, the thought presents itself that it may gently stimulate them and produce a sedative effect in the internal economy. It is not to be assumed that there is no penetrating effect of the static current in this particular method of applying it; but the hypothesis is put forward to attempt to explain how the clinical results might follow did we only get the surface charge.

2. The Static Wave Current.

This current is probably the most valuable in the science and art of electrotherapy, for there is no agent as successful in removing local infiltration or overcoming muscular spasm as is this form of static electricity. It was introduced to the profession in 1900 by the late Professor Morton of New York, and called by him the wave current, because in the completion of its circuit Hertzian waves emanating from the patient's person are produced.

In this form of treatment an electrode is placed on or over the part to be treated, the spark-gap of the machine gradually opened to the limit of the toleration of the patient—that is to say, as long as the contractions beneath the electrode are painless, these contractions being in direct proportion to the length of the spark-gap, and in inverse proportion to the area of the electrode. One point to be especially noted, which is essential in the administration of this current—for on it not only depends the comfort of the patient but the success of the treatment—and that is the rate at which the sparks cross the spark-gap. If they flow too rapidly a useless and almost unbearable tetanic contraction of the muscles is induced, while if too slowly the contractions are not sufficiently numerous to produce their therapeutic effect, and they are usually irregular and provocative of discomfort. The appropriate rate will vary within certain limits according to the area of the electrode and the sensitiveness of the part under treatment. As a general rule about 120 to 200 sparks to the minute will be found most effectual, and they should be as regular as possible. The average time for the application of the current is twenty minutes. In some cases during the last five minutes, instead of keeping the spark-gap at its maximum, the rods may be gradually opened and closed so as to produce a surging effect, thus contracting and relaxing the tissues beneath.

Turning now to the indications of the wave current. When properly applied, there is a local vibratory effect, and muscular contraction takes place. Local congestion is relieved, secretion is increased, and local pain is modified, either wholly or in part. It is indicated in almost every case of non-infective inflammation, either acute or chronic. The presence of pus, however, distinctly contraindicates its use. Inflammation is accompanied by congestion, or stasis, and it is this stasis which is relieved by the successive contractions produced by the current. It is therefore readily to be understood how wide a range of influence is possessed by this method of treatment.

The wave current is of great use in many diseases—for example, in myalgias such as lumbago, in synovitis, and in neuritis, such as sciatica.

3. The Static Induced Current.

The difference between this and the static wave current is that, whereas in the latter one electrode is attached to the patient and the positive side of the machine, the negative being earthed, therefore producing a constitutional as well as a local effect, in the static induced current two electrodes are attached to the patient, and the therapeutic effect of the current is localized between them.

The advantages of the static induced current are: first, we can get with an inferior or weak machine muscular contractions which we could not get when using wave current

from the same machine; and secondly, these contractions are obtainable without any general effect on the patient.

The local effects of this current are similar to those of the wave current, though results are, as a rule, better with the latter, which is to be preferred in the majority of cases. The static induced like the wave current is chiefly valuable for its power of contracting muscle tissue, striped and unstriped, and it is able to exercise this power even in deep-seated organs. Hence good results of this current will be seen in case of atony of the stomach, dilatation of the stomach, and ptosis with inactivity of various parts of the alimentary canal. It is in the treatment of obstinate constipation that it will be found most useful, and in certain cases where pain is present and perhaps where large electrodes are indicated, the current may be used; but in general, while it should not be forgotten, it will be comparatively seldom employed, especially when the static machine is a powerful one and all is working well.

4. The Brush Discharge.

Cavallo, in 1786, described this current as "the electrode fluid coming from a wooden point," and this description holds good to-day. If, while the patient is receiving a static charge on the insulated platform, an earthed wooden or specially made electrode be brought near him, a violet discharge will be seen passing between the electrode and that part of the patient to which it is directed. It should be held about ten inches away. At this distance the patient will feel little or nothing, and may describe the sensation as that of a cool wind. If this distance be decreased the sensation is changed to one of a stream of hot sand being directed on to the part. The violet colour is due to the fact that the discharge, in its passage through the air, renders luminous the atmospheric particles, while it is attended with the formation of ozone and nitrous oxide. The antiseptic effect of these gases is of considerable therapeutic value in the treatment of septic wounds, abscesses, or ulcers, especially when it is remembered that the current has the further effect of the stimulation of the blood supply, thus relieving local stasis, diminishing induration, and aiding in the restoration of a normal circulation. These latter effects are more important from a therapeutic point of view than are the antiseptic properties of this current, just mentioned.

In cases of neurasthenia associated with low blood pressure the application of the static brush discharge up and down the spine is usually attended with much success. In its administration especial attention should be paid to that part of the back over the region of the adrenals. The stimulation of the afferent nerves provokes an increase in the activity of the suprarenal glands, which activity tends to raise the blood pressure. Therefore this form of treatment is indicated in many ill-defined pathological states associated with low arterial tension. It acts as a general stimulant when the patient has been brought low by overwork, worry, mental strain, or bodily pain, either alone or accompanied by insomnia. For insomnia itself, with or without headache (always presuming the blood pressure be low), the brush discharge applied by means of willow broom to the top of the head gives most satisfactory results.

This current may also be used in cases of conjunctivitis, where it is applied for a few minutes by means of a camel-hair brush. In cases of non-purulent inflammation, such as acute gout, when the pain is so bad that the patient cannot bear the part to be touched, the static brush gently played over the area will soothe it in a wonderful way.

5. The Static Spark.

Even older than the history of the brush discharge is that of static sparks. It is the oldest form of static electricity on record and dates from 1734, when the Abbé Nollet first used the static spark as a therapeutic agent.

There are several varieties of spark derived from the static machine, but only one is here mentioned—the static indirect spark. It is really a current, and may be compared to a spark being discharged from a Leyden jar, the patient representing the jar. The whole of the static charge of the patient is suddenly focused to one point by the grounded ball electrode being brought near him and then discharged disruptively with the sudden appearance of light and sound. A powerful contraction of muscle and tissue at this time takes place which exercises a decompressor effect upon swollen, and engorged tissues. The violent contraction drives out fluid from the tissues, hence the alleviation of pain by reducing the pressure of which it was the cause. The instantaneous soothing effect induced by fairly long sparks—10 to 15 inches—well directed along the course of the sciatic nerve, is in some

cases marvellous, and there is nothing so peculiarly adapted to remove deep-seated congestion as this method. Furthermore, not only is the pain relieved, but the muscular spasm which so often accompanies this—and other—pain is relaxed. Another use for the static spark in neuritis as sciatica is its diagnostic value. A patient will come complaining of pain along the entire distribution of the nerve. A series of short sparks, however, will show the exact position of the lesion, for whereas these sparks are for the most part only unpleasant, when they are directed to that part of the nerve where the lesion exists the patient will immediately complain of a sharp pain, so that when this procedure has been followed treatment need only be directed to that particular part where pain was elicited.

Its capacity for causing strong muscular contraction makes it useful in preserving the tone of a muscle whose power of motion is temporarily absent or limited, or, in fact, in temporary paralysis its effect is excellent. After a short period of sparking a general as well as a local diaphoresis will be noted showing a constitutional effect, in addition to that obtained in the region to which the sparks were directed. In deep-seated trouble in large joints, sparks applied in the spaces between the bony processes, as on either side of and below the patella, will often effect relief when other measures fail.

The chief therapeutic value of the static indirect spark lies in its power to produce powerful contractions in the tissues, and the consequent squeezing out of fluid contained therein.

6. The High-Potential Glass Vacuum Tube Current.

The vacuum tube is made in shape adapted to the rôle which it is destined to fulfil. It is attached to the negative side of the machine and applied directly to the part affected. The patient feels nothing, or perhaps a slight sensation of heat. Ozone is evolved on the surface of the electrode, and as the current flows a very fine and rapid vibratory massage is effected on the part to which it is applied. Hence it is useful in restoring healthy secretion to skin and mucous membrane where this is deficient. In acne and furunculosis its effect in early stages is wonderfully specific. After the skin has been rubbed for about ten minutes with a glass vacuum electrode in action it has a distinct "ozonic" odour. Rectal ulcer and simple fissure are usually benefited. In some forms of hæmorrhoids its action is excellent. Acute capillary piles, especially if there be hæmorrhage, are relieved, with the disappearance of anal spasm, very often in one or two treatments. *Post-partum* piles with prolapse are favourable cases for this treatment. In pruritus the application of this current is often very effectual, relieving the itching from the first. It has an excellent effect upon the vocal cords, being applied with the surface electrode to the outside of the throat for about twenty minutes. Public speakers and singers find great relief when their voices have been overstrained, or if they have been using the voice when the cords were congested. The voice becomes clearer after treatment.

In gynaecology it has been extensively used with striking success in some cases and equally indifferent results in others. Much of this discrepancy may be explained by, and put down to, either errors of diagnosis or improper use. For instance, an early vaginal catarrh is quite easy to cure with this current; but where the discharge is proceeding from a diseased endometrium it is naturally of little avail. In some cases of sterility, without any apparent reason, this current has so altered the nutrition of the parts as to bring about the desired result, or, at any rate, pregnancy has followed the treatment after years of sterility. In amenorrhoea with no obvious pathology the same shaped electrode as used for sterility may be used, and the electrical stimulation of the neuro-vascular processes in the pelvis very frequently results in the restoration of the menstrual flow. In leucorrhoea, although this is a symptom of disease rather than a disease itself, especially where there is passive hyperæmia, this current is most useful, the discharge immediately losing any unpleasant odour it may have had and becoming less pungent. This current has a beneficial effect upon the whole of the female genital apparatus, relieving congestion and promoting a more healthy condition generally.

Static currents are replaceable by no other form of electricity, and, with a competent knowledge of their uses, therapeutic effects can be obtained from them which appear marvellous to anyone using them for the first time.

To get these effects consistently, however, two factors are essential: (1) a proficient knowledge of static electricity, its

characteristic effects, and of the nature of the disease to be treated; (2) a static machine of efficient power.

Some of the advantages of static electricity are, that the applications are for the most part not unpleasant, that they are perfectly safe, and that the beneficial results obtained are apparent from the beginning of the treatment.

II.—HIGH FREQUENCY CURRENTS.

BY

W. F. SOMERVILLE, M.D., F.R.F.P.S.;

Medical Electrician, Western Infirmary, Glasgow.

My thanks are due to the honorary officers for their suggestion that I should contribute to the proceedings of the Section a paper dealing with high frequency currents in their relation to medical practice. I accept the invitation the more readily as for more than twenty years I have been personally engaged in the study and use of this therapeutic agent, and I am convinced that it has a large field of useful service.

In recent years, it appears to me, there has been some want of attention to this department of Electro-Therapeutics. The capacities of x rays, of radium, and allied agencies have made a strong appeal, and no one will question the dramatic interest and valuable results which have followed studies pursued in these departments. High frequency currents can scarcely boast an equally striking series of achievements. Nevertheless, they merit attention as a means by which various forms of suffering and disability may be relieved. I venture therefore to urge that their values should not be allowed wholly to be pushed into the background by their more attractive and impressive competitors.

It has been proposed that the good effects credited to high frequency currents are due purely to suggestion. I hope here to establish the negative of this proposition; but even allowing that some element of suggestion may enter into the successful use of these currents in functional nervous disease, the practical outcome is not the less valuable. And nowadays, with the therapeutic benefits of psychological influences ringing in the ears of us all, we may hardly remove from our available resources an agency which contributes to a practical end merely because in greater or less measure it includes an element of "suggestion."

The immediate aim of the medical practitioner is to gain relief for his patient, and if this is attained he may be content, without too critical an analysis of the exact nature and mode of action of the agencies employed. Yet in saying this I am not in the least allowing that high frequency currents owe their success to a mere impression made upon the mind and emotions. On the contrary, I propose to submit evidence to show that under the influence of these currents definite physiological actions are produced in the tissues and functions of the body, and that some of these actions are capable of actual demonstration and of precise measurement; also that certain forms of organic disease are favourably influenced by the application to them of high frequency currents. This evidence I will arrange under three headings, namely:

1. The effects of high frequency currents on the surface temperature of the body.
2. Their action on tissue metabolism, as indicated by qualitative changes in the composition of the urine.
3. Their therapeutic efficacy in diseased conditions in which the element of suggestion either does not exist at all or is reduced to a minimum.

1. Several years ago I collected a series of observations made with a view to determine the physiological actions of high frequency currents, and among these were measurements of the surface temperatures taken before, during, and after the application of the currents. I shall not inflict on you either the details of these observations or the precautions taken to exclude the chance of error. It is sufficient to say that the investigation was carefully conducted, and I ask you now to consider one or two charts showing considerable modification of the surface temperatures following the application of high frequency currents.

In Chart I (1)* where the thermometer was placed on the extensor surface of the right wrist, and only 250 ma. were passed for fifteen minutes, there is a rise in the surface temperature from

* Dr. Somerville showed a number of lantern slides illustrating his paper.

82.6° to 84° F., followed, after cutting off the current, by a fall in fifteen minutes to the original temperature.

In Chart III (2) where 500 ma. were employed and the thermometers were placed on the extensor and flexor surfaces of the forearm, there is seen to be a rise during the fifteen minutes of exposure of 7.4° F. in the case of the extensor surface and 10.6° F. of the flexor surface—that is, from 81.4° to 92° F. In both cases during the fifteen minutes immediately following the cessation of the current there is a fall of temperature of 4° to 5° F.

In Chart XIV the thermometers were placed over the right brachial artery and right forearm, 600 ma. being employed, and the electrode held in the right hand only. There is a rise of temperature on the forearm from 85.6° to 103° F.—that is, 17.4° during the twelve minutes' exposure. The patient, a medical friend of my own, was unable to bear the treatment longer, as the whole upper limb swelled and the bandages fixing the thermometers were uncomfortable. During the eighteen minutes immediately succeeding the cessation of the current there was a fall of 8° F. Details of all the investigations were published in *Medical Electrology and Radiology* in May, 1906.

The last chart I will show you, by way of contrast, demonstrates the effects of high frequency currents on the internal temperature of the body. Here again a rise occurs, but to a much less amount than in the surface records—namely, about a degree and a half. The temperature was taken in the month as the patient lay on the couch, before, during, and immediately after high frequency treatment.

Now these are hard facts and they cannot be explained away. Presumably they result from modification of the vasomotor control, but whatever the explanation, "suggestion" can play no part in it. Some considerable physiological action is produced and it is produced solely by the influence of high frequency currents.

2. Changes in tissue metabolism are most confidently measured by qualitative alterations in the urine, and it was this consideration that led me to determine what influence (if any) the high frequency current exercised in this direction. Again I omit details, but have a long series of analyses which show that under treatment with high frequency currents there is produced a more normal ratio between the excretion of urea and uric acid.

Let me show you three analyses:

CASE I.

Dr. A. Before treatment, April 4th, 1905, passed 35 ounces in twenty-four hours. Specific gravity 1025; deposit, "cayenne pepper" of uric acid; very faint trace of albumin; no sugar. Urea 2.7 per cent.=11.8 grains per ounce, or 418 grains in twenty-four hours. Uric acid 0.026 per cent.=0.113 grain per ounce, or 3.95 grains in the twenty-four hours. Ratio of uric acid to urea, 1:103 (normal ratio, 1:33).

Twelve days after treatment was commenced the quantity passed in twenty-four hours was 36 ounces. Specific gravity 1022; no albumin, sugar, or deposit. Urea 2.7 per cent.=11.8 grains per ounce, or 424 grains in twenty-four hours. Uric acid 0.075 per cent.=0.323 grain per ounce, or 11.8 grains in twenty-four hours. Ratio of uric acid to urea, 1:36.

The patient was an elderly medical friend. Previous to treatment there was a marked disturbance of the normal ratio between the excretion of urea and uric acid—namely, 1:103. Twelve days after high frequency treatment had been commenced the ratio closely approximated to the normal—namely, 1:36.

CASE II.

Mr. M. Before treatment, October 30th, 1906, passed 60 ounces in twenty-four hours. Colour, clear amber; reaction, moderately acid; specific gravity 1018.5; scanty mucoid deposit; no albumin or sugar; creatinin moderate. There were no bile pigments, pus, blood, urobilin, or haematoporphyrin; while the spectroscope revealed nothing abnormal. Urea 1.9 per cent.=8.3 grains per ounce, or 498 grains in twenty-four hours. Uric acid 0.0375 per cent.=0.164 grain per ounce, or 9.84 grains in twenty-four hours. Phosphoric acid 0.19 per cent.=0.83 grain per ounce, or 49.8 grains in twenty-four hours. Ratio of uric acid to urea, 1:50. Nitrogen 240 grains. Acidity in terms of oxalic acid, 0.08 per cent., or a total of 21.4 grains. By means of the microscope only a few very minute octahedral crystals of calcium oxalate were detected.

After eleven visits for high frequency treatment, on November 12th, 1906, the quantity passed in twenty-four hours was 40 ounces. Colour, opaque, turbid, light yellow; reaction, highly acid; specific gravity 1020; copious uratic deposit; no evidence of abnormal constituents as before. Urea 2.6 per cent.=10.3 grains per ounce, or 412 grains in twenty-four hours. Uric acid 0.105 per cent.=0.485 grain per ounce, or 18.3 grains in twenty-four hours. Phosphoric

acid 0.28 per cent.=1.22 grains per ounce, or 48 grains in twenty-four hours. Ratio of uric acid to urea, 1:23. Nitrogen 230 grains. Acidity in terms of oxalic acid, 0.214 per cent., or a total of 43.4 grains. Microscopic examination showed a copious deposit of amorphous urates.

The patient was an active country gentleman. Before treatment the amount of uric acid excreted was subnormal—namely, 9.84 grains in twenty-four hours, and the ratio between the excretion of uric acid and urea was disturbed—namely, 1:50. After eleven visits the amount of urea excreted was less, while that of uric acid was increased and the ratio approximated to normal.

CASE III.

Mr. T. G. Before treatment, June 4th, 1907: quantity—an evening and morning mixed sample. Reaction, markedly acid; specific gravity 1023.5; no albumin or sugar. Urea 2.35 per cent.=10.9 grains per ounce. Uric acid 0.045 per cent.=0.196 grain per ounce. Ratio, 1:55. Acidity high, at rate of 0.25 gram oxalic acid per 100 c.cm. urine; this is nearly double the normal.

After seven applications of high frequency currents, June 12th: quantity—an evening and morning mixed sample. Reaction, acid; specific gravity 1017; no albumin or sugar. Urea 1.65 per cent.=7.2 grains per ounce. Uric acid 0.058 per cent.=0.25 grain per ounce. Ratio, 1:23. Acidity still high, though less than before—0.226 gram oxalic acid per 100 c.cm.

It is sometimes suggested that the improvement in the urinary excretion is due to nursing, rest, and careful feeding, but I have purposely selected the analyses of urines of three busy gentlemen, who were engaged in their daily work and who merely attended for treatment. Here once again we are outside the range of suggestion; at the same time we have an explanation of the sense of well-being which patients treated by high frequency currents almost invariably experience.

3. As regards the scope of high frequency currents in the treatment of functional conditions, painful or otherwise, the range is an extensive one. In a meeting such as this it would be out of place to enter into detail or to give particulars of individual cases, but I may remark in general that I have dealt successfully with numerous neuralgias of the larger and smaller sciatic nerves, the branches of the circumflex and musculo-spiral, the posterior scapular, the posterior and smaller occipital, and the trigeminal nerves. Rheumatic pains yield to treatment, and insomnia is overcome. Nervous headaches, and with them alopecia, are lessened; haemorrhoids, fissure in ano, and pruritus ani are relieved if not cured; skin affections such as eczema and acne, and even psoriasis, are benefited. Choric movements subside, chilblains disappear. Asthma is often controlled, strumous glands decrease, and ulcers are healed. Incontinence of urine in both old and young is overcome. The pain succeeding fracture is subdued.

My purpose in this paper has been simply (1) to show that high frequency currents do actually occasion measurable changes in the physiological balance of the human body, and (2) to indicate that, apart from so-called functional disease, these currents afford therapeutic help in certain conditions where there is without question definite organic disease.

DISCUSSION.

The PRESIDENT asked whether low blood tension was not a contraindication to static treatment; also whether the openers of the discussion had had any experience in the treatment of x-ray burns as treated by the effluve. It would also be interesting to know what Dr. Humphris meant by his expression an "efficient static machine." The speaker was one of those who in the early days took up high frequency and similar work, but he had been, unfortunately, overwhelmed by radiology. He was sure, however, that there was a great deal of value in these methods in properly selected cases.

Dr. HOWARD HUMPHRIS, in reply, spoke of the criticism which had been made on other occasions that the effects of these currents were due to suggestion. He had demonstrated by means of a potato and also a piece of meat—neither of which could respond to suggestion—that there was no doubt as to the actual introduction of heat into the tissues. Not only in high frequency but in ordinary galvanic applications it might be that the great majority of the effects were due to heat. An efficient static machine he would define as a static machine capable of being revolved at a rate which would produce a spark half the diameter of the plate. The spark, between the gaps should be equivalent to, or little short of, the plate radius. As for the treatment of x-ray burns by the

effluve, in theory it might appear that this was an efficient treatment, but the cases of x -ray burns with which he had had to do were treated by other means, preferably carbon-dioxide snow. Although electricity was old x -ray burns were now, and he thought that static electricity should only be used where the indications for its use were quite clearly defined and well established. In reply to a further question, he said that for high blood pressure there was nothing like the auto-condensation couch. Of course, it was very important to know before commencing treatment whether the pressure might not be compensatory.

X RAYS IN DISEASES OF THE SKIN.

BY
E. W. REED, M.D. LEEDS,

Honorary Director, Radiotherapeutic Department, Manchester and
Salford Hospital for Diseases of the Skin.

THE time has arrived when the value of x rays in the treatment of skin diseases should be more generally known by the practitioner than it is at present. It is in many cases not only a definite cure, but by far the best means for obtaining that cure; and occasionally it is the only treatment when all other methods have failed.

The textbooks on dermatology are stinted in their praise of x -ray treatment, and in no condition do they recommend it as the first thing to try, but prefer to enumerate all the ointments and lotions in the Pharmacopoeia, irrespective of the discomfort caused to the patient or the ruin of his under-clothing. Take, for example, psoriasis: the usual ointments only temporarily cure the complaint, but permanently ruin the clothing; now x rays will remove the eruption more quickly than the ointments, and the saving of the clothes will pay the x -ray fee. Textbooks on radiotherapy are vague and unconvincing when dealing with skin disease, and yet I cannot imagine any treatment of recent years more satisfactory in its present results, and more promising for future research.

Skin diseases are a side-line in most of our big teaching hospitals, and the student is expected to diagnose any case after about a dozen lectures and a similar amount of clinical experience. He cannot be blamed, seeing how much general knowledge he has to cram into so short a time. The fault is that there are so few men who specialize in this important branch of medicine, in comparison with the large number of sufferers; and hence the verdict "incurable" which has to be pronounced so often in cases of lupus, rodent ulcer, and many other skin diseases, where an early diagnosis would have meant an early cure. The inability to diagnose and treat applies to many of the less serious diseases, which are the unnecessary cause of pain, discomfort, and loss of work.

In this paper I do not venture to tell you how to diagnose skin diseases, but prefer to remain one of the angels who "fear to tread," as this is distinctly the realm of the dermatologist; but as medical men we ought to know the difference between an acute and chronic inflammatory condition; and assuming that we are able to discriminate between these two stages of skin disease, I propose to tabulate the various conditions which should indicate the prompt application of x rays. If the diagnosis of a dermatologist can be obtained, and collaboration with him is possible, by all means get it; but even then there are two things which must be insisted upon, and these are, first, that the dose must be prescribed by yourself, and secondly, no other metallic treatment must be given externally while the x -ray treatment is being given.

The first condition is obvious, and the second is because of the ill effects of metallic ointments or lotions covering or impregnating the skin. They may act as a wall or barrier to the rays, or their metallic secondary radiations may greatly intensify the action of the primary rays.

The secondary or more correctly characteristic radiations which are given off from metallic particles after being impinged upon by a beam of x rays, are practically unknown, except to the radiotherapist and the physicist. These rays are very soft, intense, and easily absorbed by the skin, and often account for patches of lupus breaking down, not because of the amount of primary rays they have received, but because of the prolonged metallic ointment treatment they have previously had, and the secondary radiations thus set up. X rays of course are blamed or their use discredited.

I believe these characteristic secondary rays are the clue to future successful research in the treatment of skin disease, chiefly because of the homogeneous nature of these rays. We know that a beam of ultra-violet rays when passed through a spectroscopie is analysed into a series of rays of different wave-lengths; and these, if directed on to a film of bacteria, will produce lines similar to those produced upon a photographic film. These lines are due to the bacteria being killed, inhibited, or stimulated according to the wave-length of the particular ray which strikes them. Thus, rays of different wave-lengths have widely different therapeutic effects, and this applies to x rays; some with certain wave-lengths are wanted and others are not. Obviously, then, the thing to find out is the characteristic homogeneous ray, if any, which acts most beneficially upon each disease. This can only be done by getting the metal whose characteristic ray you want into the affected skin by injection, ionization, or by any other means, and filter out all the primary rays from your treatment tube, except those which will excite that particular metal. The trouble, I find, is getting the metal into the skin, but I have no doubt that others will be more ingenious than myself and therefore get better results. We do know that a small patch of lupus which has previously had zinc ointment well rubbed into it before x -ray treatment does better and heals more quickly than one treated without the ointment; this must be because of the secondary radiations.

How do x rays affect the diseased skin? We do not know this, any more than how ordinary sunlight affects the skin. We know only that it is by the absorption of these rays, and the conversion of their energy into some other form of energy of a lesser wave-length—namely, a degradation of wave-length. This effect, if suitable quantities are absorbed, results in a healthier condition, which enables the skin to fight invading micro-organisms and toxins, and to dispose of excessive degenerative tissues. Occasionally larger doses are given, with the object of directly killing neoplastic tissue, which from experience we find will be destroyed before the surrounding normal tissues are. The normal ones will then throw around a barrier of fibrous tissue, which finally takes the place of the neoplasm. This fibrous tissue formation after prolonged radiation is of great value in combating many forms of malignancy, but must be regarded as bad treatment, or I might better describe it as overtreatment, in the less serious conditions of chronic inflammation, where stimulation and absorption only are required.

Time is too short to discuss the technique of x -ray treatment, except briefly to say that a medium soft tube is the best, a gas tube of about 4 inches spark-gap, or a Coolidge tube with about 6 inches spark-gap—that is, if they are excited by a coil installation, which I think is the preferable means. The distance of the part treated from the tube should be kept as uniform as possible in order that the operator can estimate the exact dose he is giving in each case. If the treatment is likely to be a long one, as is often the case in old-standing diseases such as scrofuloderma, lupus, and eczema, remember that there is a saturation stage to a particular radiation—a stage at which the skin has absorbed all the rays it can healthily deal with, and any more of the same type are either useless or act as irritants. In order to overcome this, I alter the thickness of the filter every few weeks, and in this way am able to carry on longer and maintain the improvement which would otherwise have ceased. It is a simple point, but very effective. Starting with no filter, I add 0.5 mm. of aluminium after every four doses up to 2 mm., and work back to *nil* again.

Conditions contraindicating x -ray treatment may be divided into the following:

- General, such as grave blood diseases, and disease of the blood vessel walls, and
- Local, which includes acute inflammatory diseases of the skin and haemorrhagic skin troubles.

The symptoms and appearances of diseased skin which indicate the prompt application of x rays may be put under six headings:

1. Indurations and thickenings;
2. Itching;
3. Chronic infiltrations;
4. Lichenification;
5. Conditions requiring depilation; and
6. New growth.

These conditions, one of which is only a symptom—namely, itching—are easily detected, but as you know, they are present in a very large number of skin diseases, and

wonderful opportunity for the radiotherapist, because the results are cures in the vast majority of cases, also the treatment is pleasing from the patients' point of view, because it is neither painful, troublesome, nor destructive to their clothing. To get the best results courage is required, tempered with caution, which is only got by experience.

1. *Indurations*.—These are best seen in acne indurata, and about twelve to sixteen doses will flatten down a face to a decent smooth soft skin, which before was a mass of lumpy thick-walled abscesses. Some of the abscesses may have to be incised and emptied. All forms of acne do well under x rays.

Thickenings, such as are seen in keloidal formations, respond well to the same treatment, but sometimes require perseverance, even up to twelve months, and complete flattening will result. In these cases always rest after the slightest sign of reaction, and always keep altering your filtration. The thickenings associated with scrofuloderma do excellently, in addition to the treatment being the best possible one for the infected tuberculous glands or other tuberculous focus associated with this disease.

2. *Itching*.—This symptom responds more quickly to x rays than to any other remedy if the itching is not of parasitic origin. It should always be tried first. You can in almost every case of this kind, when it is not associated with a skin eruption, promise complete relief, or considerable abatement, after four weekly three-quarter pastille doses, but a further three to four pastille doses should be given after all itching has disappeared. Pruritus ani and pruritus vulvae are frequently complained of, and will respond quickly, even though the condition has been of many years' duration. The itching which is so often associated with skin diseases is usually relieved after a few doses, and, the scratching having ceased, the chronic inflammation soon subsides.

3. *Chronic Infiltrations*.—These are frequently observed in cases of eczema, especially the localized types, and a few radiations will soon stimulate a healthy reaction. Take, for example, those obstinate cases of eczema nuchae. Here we have violent itching as well as infiltration, and frequently, when every other remedy has failed, the rays will act like a charm and a quick cure result. Care, of course, must be taken not to cause baldness where the disease has invaded the hair at the back of the head.

4. *Lichenification*.—This is a condition which often follows upon a patch of eczema, and is characterized by some thickening, dryness, and often slight roughness, and sometimes rising scalliness, with accentuation of the lines of the skin, and with, in most instances, closely crowded or coalescing, light, flat, dull-reddish papules, usually caused by friction, scratching, and possibly to some extent to local medication. X rays quickly clear this condition.

5. *Conditions requiring depilation*, such as ringworm and yecosis, have so extensively proved the value of x rays as the best agent to adopt that further recommendation from me is unnecessary.

6. *New Growths*.—In cases of epithelioma, x rays should never take the place of excision where this is possible; it is always advisable to follow excision by a few doses of the rays.

In the case of rodent ulcer, excision is unnecessary because permanent cure can be effected by a simple erosion followed by suitable x-ray treatment, a flat pale scar being the only trace of the previous ulceration. The method I adopt at the Manchester Skin Hospital is erosion of the rodent tissue, followed by full pastille doses, on three or four consecutive days—three for the smaller ulcers, and four for the larger ones. The area treated overlaps the rodent tissue by about one-eighth of an inch all round. The distance of the ulcer from the anticathode is seven inches, and the pastille is placed half-way. The results are excellent, and cures are obtained in practically every case, unless periosteum or cartilage has become involved, or the cases have been subjected to previous intermittent x-ray exposures over a long period. In these latter cases the fibrosis produced by the rays seems to take all the "kick" out of the tissues which appears necessary for the healing of rodent ulcers.

I do not doubt the good results obtained by radium, but an overdose of radium has much more serious consequences to the surrounding tissues of an ulcer than x rays have; and is, I consider, indicates the latter agent as being the more desirable one.

The further progress of an incurable rodent ulcer can be delayed for years by x-ray treatment, but this has not been my experience with radium.

DISCUSSION.

Dr. WOODBURN MORISON (Manchester) said that in treating pruritus ani a method was followed at Manchester which had been introduced by Pirio of Montreal. The patient was treated from below upwards while seated on the couch. A pad of cotton-wool was placed in position so as to give an oblong area where it was desired to treat, and the patient sat with the buttocks separated by the pad, a coin was used to indicate the focus for the rays, and the rays were directed from the tube below.

DIFFERENTIATION OF ACTIVE FROM QUIESCENT
TUBERCULOSIS OF THE LUNG.

BY

JAMES CROCKET, M.D., D.P.H., M.R.C.P.E.,

Lecturer on Clinical
Superintendent,
CottUniversity Medical
Scotland and

The utility of the x rays in the diagnosis of pulmonary tuberculosis has been abundantly proved.

Unfortunately for patients, the profession as a whole has not yet come to recognize its importance and to avail itself of the help that can be obtained thereby. Apart from the inconvenience of sending patients to the radiologist, two reasons may be adduced for this, namely:

1. The difficulty of interpreting x ray plates of the lungs. To many general practitioners a radiogram of a fracture is like a letter in their mother tongue. The sharp clean-cut edges of the break are usually easily seen and interpreted. A radiogram of the chest, on the other hand, is like a letter in an unknown foreign language. The lines and shadows, normal and abnormal, mean nothing to them. The least even with difficulty is recognized. The ribs alone indicate the area under observation.

The remedy, of course, is to drill the medical student in the interpretation of radiograms during his curriculum.

2. The inability of the x rays definitely to diagnose tuberculous disease in its earliest stages, and therefore their failure at that particular period when they could be of the very greatest value. Early tuberculous lesions are not gross—there is no infiltration, no fibrosis, no caseation. Congestion, cell proliferation, and cell destruction alone are found. These the x rays with ease penetrate, and no shadow is caused on the x-ray plate. The signs of early tuberculosis are not those of consolidation or increased density, but those of irritation and toxæmia—lessened functional activity of the lung and of the diaphragm, impaired mobility of the chest wall, increased muscular tone, vasomotor instability, lethargia, etc. Clinical facts undoubtedly indicate the presence of tuberculous lesions of the lungs prior to radiography.

The decision, therefore, as to the presence or absence of early tuberculosis is not a matter for the radiological laboratory to decide, but for the clinician with all the facts relative to the history of the case, the physical examination of the patient, and the chemical, cytological, and bacteriological investigation of the sputum before him, along with whatever negative or positive evidence has been derived from x rays.

In the diagnosis of active from quiescent tuberculosis of the lungs by x rays one must call to mind the stages traversed in the production of the disease and in the process of repair. There are, one might say, three stages in the production of the disease and three stages in the process of arrest.

The stages in the production of tuberculosis are:

1. The implantation of the organism and the development of a tubercle.

2. Local necrosis and the formation of a caseous nodule.

3. The rupture of the encapsulating membrane of the nodule and the production of an ulcerating cavity.

In all cases when active disease is present there are three associated conditions—congestion, alveolitis, and a local lymphocytosis. These are responsible for many of the signs on physical examination.

The three steps in the process of repair of tuberculosis of the lungs are:

1. Delimitation and localization—the congestion, alveolitis, and lymphocytosis disappear.

2. Fibrosis and calcification—the production of epithelioid cells and fibroid tissue secure ascendancy over the necrotic processes. As a result the affected area is walled up and shut off, and the caseous matter undergoes dehydration and calcification.

3. Contraction of the affected area and subsequent alteration of the general orientation of the thorax.

In all cases where lung tissue has been destroyed and healing has taken place we have compensatory hypertrophy and emphysema. This is specially marked adjacent to the affected area.

Seven conditions caused by tuberculosis may cause shadows in a radiogram of the lungs: (1) congestion of the blood and lymphatic vessels; (2) alveolitis in the neighbourhood of the affected area; (3) local lymphocytosis; (4) the infiltrated proliferated epithelioid cells; (5) fibroid tissue production; (6) caseation; (7) calcification.

The degree of density produced by these depends on their extent and their distance from the plate, and, generally speaking, is in the order in which I have given them. Which are indicative of activity? How do the shadows produced by active lesions differ from the shadows in quiescent disease? Can one definitely state by examining a radiogram that there is active disease present?

The first three or four conditions that I mentioned are alone indicative of activity—congestion, alveolitis, lymphocytosis, and epithelioid cell production. These produce, if anything, faint cotton-wool ball-like shadows, shadows resembling the cirrhone clouding that one sees in the sky on a summer day. The shadows caused by fibrosis, infiltration, caseation, and calcification are dense and dark.

In cases of acute or subacute phthisis, and in cases of chronic disease with a recent exacerbation, it is possible to state definitely that active disease is present. The wool-like shadows of alveolitis, congestion, and lymphocytosis are pathognomonic. In chronic fibro-caseous tuberculosis, where the shadow is dark and there is little wooliness or mottling, it is impossible in most instances to tell from a single radiogram whether or not the disease is active or quiescent. Then one's decision will be based on two things: (1) clinical facts of the cases; (2) serial radiograms.

Patients suffering from active tuberculosis always give symptomatic evidence, and usually have definite signs present. On inspection we get spasm of muscles of the chest wall, excessive sweating, coldness of the hands, and dry skin and we may get granular, cog-wheel, or weakened respiratory murmur and subcrepitant or mucous râles. Auscultation may be negative. One should not trust to it. Lethargia, a low blood pressure, an adverse influence of exercise on the temperature and the pulse, are all indicative of activity. If there be no signs and no symptoms, no matter what the radiogram shows, there is no active disease in the lungs. Presumably, of course, a trained eye, ear, and hand decide the presence or absence of those signs and symptoms. Serial radiograms are very useful and very suggestive. Patients suffering from chronic tuberculosis of the lungs should be radiographed periodically, just as patients suffering from cardiac disorders have pulse and heart tracings made and filed for reference and comparison.

It is very interesting to trace radiologically the development of tuberculosis as it is advancing.

1. There is diffuse haziness of the affected area, and enlarged trunks radiating from the hilum. This haziness is best made out by radioscopy, using a low milliamperage and a small diaphragm. It may not come out at all on a radiogram.
2. The trunks become more accentuated, and budding—rounded or oval in form—appears on certain branches, particularly the upper branches. These buds are better seen by radioscopy than by radiography.
3. The buds become more numerous, becoming larger and more dense in the centre.
4. The buds coalesce and become cloud-like, particularly marked towards the hilum.
5. The shadows become more dense; diffuse mottling is usually seen peripherally.
6. The whole lung may become dark except for rounded clear areas significant of cavity formation.

A ring shadow may appear in the lung without previous consolidation. We have three such cases at Bridge of Weir Sanatorium at present. Infiltration, rapid disintegration, with little or no collateral inflammation and effort at encapsulation may account for this. The period required for the disease to develop from the hazy to the cotton-wool-ball stage, and from the cotton-wool-ball stage to that of opacity, varies greatly from a few weeks to a few years, depending on the resistance of the individual.

In a case of retrogressive disease one finds:

1. Disappearance of the mottling and haziness generally. There may persist a fair amount of haziness, due to thickened pleurae.

2. Development of greater density. The edges of the areas are sharply cut. This is largely due to the emphysema.

3. Retraction of the dull areas. They become smaller and ultimately less opaque.

4. Widening of the interspaces and freer movement of the ribs and diaphragm.

In a radiogram of moderately advanced active tuberculosis of the lungs one can usually make out at one part evidence of progressive disease, and at another evidence of retrogressive and quiescent disease.

By a series of radiograms of an individual one can tell definitely how the disease is progressing—favourably or adversely. In a case of doubt it is good practice to take radiograms from the anterior and posterior aspects at least. Personally I frequently also take one especially of the apices and two of the lungs, each lung separately. This should be repeated in a month or six weeks. Comparison of these radiograms enables one to decide whether immunity is being established and quiescence obtained.

To sum up:

1. Radiography does not show the presence of the earliest stage of active tuberculous disease of the lungs. Radioscopy may reveal it by a diminished translucency and by certain changes, particularly lessened mobility of the chest wall and a staggering diaphragm.

2. Acute and progressive tuberculosis shows itself by the presence of budding and cirrhone clouding, and by accentuated trunks radiating from the hilum. These are caused by hyper-vascularization chiefly.

3. In chronic fibro-caseous tuberculosis a single radiogram frequently fails to determine the question of quiescence or activity. Serial radiograms at intervals of four to six weeks indicate progression, adverso or favourable, and quiescence.

4. Radiography should be used simply to amplify. It can never supersede clinical methods in the diagnosis of tuberculosis of the lungs, and in determining its activity or quiescence.

POINTS IN THE DIFFERENTIAL DIAGNOSIS OF SIMPLE AND MALIGNANT BONE DISEASE.

BY

C. W. SCOTT SABERTON, M.D. MANCH., D.M.R.E. CAMB.,
Honorary Radiologist, Harrogate Infirmary and Royal Bath Hospital.

[Abstract.]

DR. SABERTON'S paper was accompanied by a number of lantern views showing the x-ray appearances in the cases to which he drew attention. He spoke first of the comparatively rare disease known as osteitis fibrosa or fibrous osteitis. Very little was known of the pathological changes in this disease, and nothing as to its cause. In some cases trauma appeared to be an etiological factor. The disease seemed to be due to some constitutional peculiarity of the bone or osteoblasts, and a gradual conversion of the compact bone into fibrous tissue took place. The bone most frequently involved seemed to be the tibia. The salient clinical features of the condition were as follows:

Frequently only one bone was affected; there was liability to sudden fracture from slight injury; the shaft of the affected bone was bowed, and this was associated in some cases with expansion and egg-shell crackling; the patient usually complained of pain and aching in the affected limb.

The author then showed radiographs illustrating the early and late stages of the disease. In one case the patient—apparently a healthy male—gave a history of a feeling of weakness in the left leg, with swelling of the limb following fatigue. One day, while watching a cricket match, he stepped backwards, heard a crack, and fell with a broken leg. It was reported that in some cases following a fracture the bone recovered its normal condition. The author personally had not seen a case in which a return to normal occurred, but the fractures united firmly again, and apparent arrest of the disease took place. One patient, a female, was very crippled, and gave a long history of gradual bowing of the left tibia. Recently an egg-shell crackling had appeared over the tubercle of the tibia and inner side of the upper part of the shaft. This area was tender on pressure. The radiograph showed the obliteration of the medullary cavity, the curious changes in the compact bone, and the great variation in density when the disease was advanced. There was a fracture through the upper part of the shaft, and the radiographic appearances in this area suggested possible malignant degeneration. The limb was amputated.

It was important not to confuse osteitis fibrosa with certain other diseases which might simulate it, and in arriving at a diagnosis the clinical history had always to be considered in conjunction with the x-ray findings. The chief diseases to be considered in arriving at a diagnosis were:

1. Osteomalacia. This disease occurred most frequently in females, and was associated with pregnancy and lactation. Clinically a large number of bones were involved.

2. Osteitis deformans (Paget's disease). Usually many bones were affected. This was a disease of the middle-aged and elderly. Spontaneous fracture was not common. Some cases had been reported of a mono osteitic type—that is, single-bone involvement. It occurred to him that this type might be really osteitis fibrosa, and not osteitis deformans.

3. A septic arthritis might present bony changes on radiographic examination simulating osteitis fibrosa. One patient suffered from a septic arthritis of the right knee-joint, which was thought to have been caused by a blister on the little toe. The absorption of the articular cartilages showed the case to be one primarily of arthritis, with secondary changes in the adjoining bones.

4. Chronic osteitis and syphilis. These diseases were usually characterized by marked periosteal overgrowth and increase of the cortex at the expense of the medulla.

In connexion with the last of these categories the author showed lantern views of an interesting case in which a possible sarcoma of the lower end of the femur had been suspected, but the radiographic appearances did not support that view. The conclusion he had arrived at was that the condition was either due to congenital specific disease or to some disease of the pituitary.

5. Osteomyelitis. This disease was associated with periostitis and the formation of bone abscesses and sequestra. Occasionally cases were met with which did not present all the classical features and in which a diagnosis was difficult to arrive at.

6. Malignant diseases of bone: (a) periosteal sarcoma; (b) carcinoma of the head of the humerus.

The author showed illustrations of both these cases. A typical example of periosteal sarcoma was in an apparently healthy child, 12 or 13 years of age, who was brought for x-ray examination of a swollen knee-joint. The leg, unfortunately, was not amputated, and the child had a most painful and distressing ordeal. At the time of death, six months afterwards, the growth was almost as big as the rest of the body. Carcinoma of bone generally followed a primary lesion elsewhere. A patient who had had her breast previously removed for malignant disease, and was suffering from neuralgic pains radiating down the arm, was examined by x rays. The radiogram of the shoulder-joint showed evidence of a destructive process involving the head, great tuberosity, and upper part of the shaft of the humerus. Numerous scattered deposits were also present in the right lung.

7. Cystic disease of bone. The cystic condition of bone might be a very slow form of chondrosarcoma or myeloid sarcoma.

There were many other interesting bone conditions, some of them presenting difficulties in diagnosis, but it was not possible to deal further with this large subject in a short paper. He added that spontaneous fracture, or fracture from slight injury, might occur in other diseases of the bone, such as sarcoma, secondary carcinoma, osteomalacia, bone cysts, fragilitas ossium, and in cases of simple atrophy, either simple or the result of disease. Not long ago a case was sent to him for examination for the fracture of the radius and ulna caused by the patient merely resting one hand on the mantelpiece while stooping to light a piece of paper in the fire. The bones, so far as he knew, never united again. No definite pathological change could be seen in the radiogram to account for the fracture or its non-union.

DISCUSSION.

The PRESIDENT said that while it was generally quite easy to distinguish by radiological means diseased from normal bone, it was not always so easy to say whether a particular disease was simple or malignant. That was the first question the radiologist had to answer. One would have liked to have heard more of Dr. Saberton's views with regard to the fundamental differences in the structure of bone which led to the diagnosis on the one hand of a simple disease and on the other of a malignant.

LEAD-GLASS SHIELD FOR COOLIDGE TUBE, AND THE BUCKY-POTTER DIAPHRAGM.

BY

H. E. GAMLEN, M.B., B.S. DURN, D.P.H.

[Abstract.]

DR. GAMLEN, who accompanied his paper by an exhibition of the protective devices in question, expressed the view that x-ray protection was carried too far, and that many of the troubles attributed to radiation were due to the high-tension discharges and impure and overheated air of the x-ray room. The expensive protective apparatus with which the market had been flooded were in many cases unnecessary, hindered the work, and by their very appearance had a disturbing effect on patients. The glass protection shields as generally supplied were badly moulded, the pieces were of unequal thickness, and protected only the sides and bottom of the tube, leaving the top and ends bare.

He himself worked several hours daily with the Coolidge tube, generally at the fullest possible voltage, and he found it necessary to protect the anode and cathode ends by means of lead-glass sleeves and the top of the open shield by a thick-lined lead-cloth cover. To keep the tube cool a rubber tube in the lid was connected to a powerful fan motor. This method, however, proved cumbersome, and he approached the glass manufacturers of Great Britain and Belgium with a view to the manufacture of a heavy leaded protection shield, sufficiently large to enclose entirely the 7-inch Coolidge tube. None of the makers would undertake this, their excuse being its weight and cost. Finally, he sent his specifications to America, where a shield was made such as he now produced before the Section. He claimed that the shield was a great improvement on any on the market; it was not heavy, and could be moved freely in every direction. An air-blast kept the tube cool, the current of air working from the cool cathode end over the x-ray bulb and out at the hot cathode end, where it had free exit. This arrangement had been worked by him for hundreds of hours, and no tube had ever sparked through it. The lead equivalent of the glass was one-sixteenth of an inch (1½ mm.) of lead, and was in excess of what was generally supplied in this country and in America. He had tested this with his ionizationmeter and found it correct.

When this shield was installed the operator might walk freely about the room during the time the tube was in action. He had placed Kienböck strips at a distance of six feet from the tube, and the radiation after three hours only acted upon them to the extent of No. 2 on the Kienböck scale; he calculated the erythema dose of the rays from a Coolidge tube working at 9-inch gap and passing through a filter thickness of 1½ mm. at from 24 to 30 Kienböck, so that it would take at least forty-five hours at this distance to cause a dermatitis.

So far, in deep therapy, it had been impossible to protect fully by means of a glass shield; the best protection was afforded by standing behind a lead shield ¼ inch thick. He had intended to have a similar lead-glass shield made for the protection of a 16-inch Coolidge tube as used in deep therapy, but abandoned the idea on finding that his 16-inch Coolidge tube would not stand the necessary high voltage from the coil outfit.

The Bucky-Potter Diaphragm.

The speaker then went on to describe the Bucky-Potter diaphragm, the function of which, he said, was to absorb the scattered rays which were generated within the tissues of the body, and which differed only slightly from the primary radiation. In the past the only effective way to limit their action was by the use of compressors and diaphragms. The Bucky-Potter diaphragm was on a different principle; it did not restrict the intensity of the ray volume, but it prevented the secondary rays already formed from reaching the film or plate, thereby resulting in better contrast and definition.

The diaphragm or grid consisted of a mechanism moving during the whole exposure between the body of the patient and the photographic plate. The grid itself was made up of strips of lead alternating with strips of wood compressed together. The grid was so shaped that every part radiographed came under its action, the metal being spaced to allow the greater part of the primary rays to pass, while obstructing the secondary radiation. The normal distance between plate and tube was twenty-four inches. The moving mechanism was by means of strong springs, and the speed of movement was governed by the size of the aperture of an oil pump, which was set in action by the pulling of a cord.

The time of exposure was from two to three times the normal. Double intensifying screens and double-coated films were necessary for its rapid working.

DISCUSSION.

Dr. ROBERT KNOX (London) said that it was reckoned that 3 mm. of lead was required to give anything like adequate protection, and with the penetrating rays which seemed likely to be used in the future it was probable that greater protection even than this would have to be put in. In the future radiologists would have to work to maximum protection by shutting in the radiation as much as possible and getting rid of the more elaborate devices which Dr. Gamlen had referred to. In France he believed that oil was largely used as a medium of protection. It was important to remember that damage might be produced by radiations which did not cause the slightest trace of dermatitis. The dermatitis was the manifestation of an underlying effect, the first onset of which was to be avoided if possible. One should not wait for the dermatitis before arranging one's precautions. A good many of the cases in which there had been blood changes following x-ray exposure had developed without any dermatitis whatever.

Dr. WOODBURN MORISON (Manchester) said that of course there could not be absolute protection. The diaphragm had to be opened if the tube was to be used at all. Even with an absolutely protected tube box, save for the rays coming from the diaphragm, the moment the diaphragm was opened there would be x rays in every part of the room. He thought that the abdomen was the part of the body which the x-ray worker should take most pains in protecting. A great deal of the damage done by the radiation was done by that radiation which came out via the diaphragm and struck the abdomen of the operator. The protective arrangements in the x-ray department of the Manchester Royal Infirmary were at one time deplorable, and a colleague of his found himself suffering from chronic diarrhoea. An arrangement was made, whereby quite good protection was secured, but his colleague, on returning to work after an interval, had a recurrence of the trouble whenever he started screening. But as soon as he began to wear a leaded apron both back and front the trouble disappeared.

Dr. GAMLEN pointed out that the shield he had shown to the Section was intended only for use during x-ray treatment.

THE X-RAY TREATMENT OF TINEA TONSURANS.

J. GIBSON GRAHAM, M.A. GLASG., M.D. EDIN.,
Physician, Electrical Department, Elder Hospital, Govan.

In no department of x-ray therapy have x rays won a more decided triumph than in the treatment of tinea tonsurans. After an experience of over twelve years I can speak with some confidence of the results, and, although many workers have handled far more cases, yet I have treated many hundreds and have been in a position to keep in touch with a considerable number of my cases for years.

I propose to give the results of my individual experience in the hope that they may be of more interest than a mere review of the experiences of others. I began in the days when the naked tube was used, and passed on to specula and pastilles, and to the Adamson method, which is still the method I employ, with a slight modification, to which I will refer in a moment. In a paper like this it is not necessary to say more of the method than that by means of it the whole scalp is irradiated from five centres. Instead of the tripod arrangement I have used for several years past a single central leg or pointer made of wood. This allows me to regulate better the angle of my tube and get it more quickly into position, but it has the disadvantage of leaving a small tuft of hair unexposed unless one gives an additional dose through a fine glass speculum. There is now on the market a single pointer made of a material which does not possess this disadvantage. I use a hard tube, with equivalent spark-gap of 7 to 8 inches. A soft tube is of no use, and failures in this direction of underexposure are most often due to this cause.

I got satisfactory epilation with an exposure of eight minutes. The hair begins to loosen in fourteen days, and in from eight to fourteen days further the scalp is completely bald, smooth, and shining. This is what occurs in a typically successful case, but occasionally, in a small number of cases,

and within a week to a fortnight of the exposure, an eruption of pustules, small subcutaneous abscesses, and subcutaneous indurations has occurred. The hairs, however, loosened in the usual time, and regrew well after the inflammation and suppuration were removed by treatment. There is another condition of a similar nature which I illustrate by quoting from a case of my own:

A girl, aged 9 years, had the whole scalp affected. The usual ointments were vigorously applied for a month. She was treated on December 9th and 10th, 1919, and on December 24th hairs were noted loosening all over the scalp, and there was some erythema. On December 31st the affected areas were covered with scales or crusts which could be pulled off with the hairs, leaving a moist red surface underneath. This demanded some treatment, and ultimately did quite well.

Again, I have had cases in which dry scales formed in the affected areas, or some of them, and were very persistent, but ultimately these cases were satisfactory. These complications are, I think, to be attributed to the irritant applications to which the scalp has been exposed before x-ray treatment has been undertaken. The x rays are, no doubt, contributory owing to their devitalizing effect on the scalp tissues, allowing the invasion of pyogenic or other micro-organisms. The scales or scurfiness which I have noted may be due to the effect of the rays on the sebaceous glands of the scalp, paralyzing their function, and thus bringing about the dry, scaly condition, which, as I have said, may be very persistent.

Evidently two of the conditions to which I have referred can be obviated if the x-ray operator could get into action *ab initio*. In some cases I have had, in which there was no previous treatment, the results were all that could be desired. Some medical men in Glasgow have been so satisfied with results which they have seen that they have their ringworm cases treated at once by x rays, but I fear this is not to be expected generally, and therefore the x-ray operator should see that time is given for the effect of irritant applications to subside and cleanse and soothe the scalp for a week or so before applying the rays.

I have had cases in which small patches of permanent alopecia resulted from exposure to x rays in the treatment of tinea of the scalp. These occurred some years ago, when I had not gained the experience which comes through practice. One was a patch, the size of a shilling, on the right parietal region; otherwise the hair growth was excellent, but this patch has remained for years, as I have verified personally. Another was a case which I had to irradiate again because the first exposure was insufficient. A permanent bald spot, the size of a five-shilling piece, was left on the frontal region; otherwise regrowth of hair was excellent. This case I have seen many times, years after the treatment.

These instances denote the danger which is to be avoided. As an operator gains experience the possibility of such an occurrence is reduced to vanishing point. Nurses or unqualified people should never be allowed to treat ringworm of the scalp with x rays. The worst case of permanent alopecia I have seen occurred in a case treated by a nurse.

Some years ago a distinguished radiologist and electro-therapist warned the medical public of the dangers of the action of x rays on the delicate nerve cells in the brains of children treated for ringworm. I have been able to keep in touch with many of my cases for years after treatment, and I have treated young children under 2 years; I have never seen any sign of impaired mental function attributable to the x-ray treatment, nor have I seen a report of such a case.

DISCUSSION.

Dr. W. MITCHELL (Bradford) said that he had been very much interested in hearing of Dr. Graham's experience, which largely coincided with his own. He had not had a single failure to cure, nor a disaster of any permanent kind, although in his early days he used to go about the streets of Bradford dodging bald-headed people. He elaborated a very simple plan for security. Like Dr. Graham, he believed in working with a very hard tube. He used a tube with a light anode. He believed also in allowing a fair margin for error. Therefore he worked with a low milliamperage and used a thin filter, placing the pastille under the filter, and getting four-fifths of the "B" dose; he also used a Kienböck adapter. He found pustular eruption quite common, and his own view was that there was some stimulating action on the staphylococci. He found no bad after-effects, except in a very small percentage of cases. He was quite certain that the x-ray treatment of tinea was the most satisfactory and certain method available.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

BILATERAL COLOBOMATA OF THE MACULA.

Mrs. A., aged 30, complained that his vision had been defective for years; he stated that he was unable to read, and that if he fixed his eyes in the direction of an object he could not see it, but that he could, indistinctly, see things to one side of him, also that he could get about at night fairly well, and even during the day did not stumble over objects in the line of his defective vision. His family history was negative. His vision with both right and left eyes was for hand movements only. Retinoscopy showed both eyes to be emropic, but no improvement was obtained with glasses. His nasal fields showed large central scotomata in both eyes; the peripheral fields could not be reliably taken owing to the loss of central fixation, but he appeared to see large white objects in the periphery of both fields. The cornea, iris, lens, and vitreous were normal in both eyes. The fundus of both eyes showed a pearly-white depressed area, at the centre of which would have been the macula. The defect was nearly circular, and measured about two discs in diameter. The vessels were steep and sharply defined; the base was about 1/2 lower than the surrounding fundus; traversing the base were some large straight vessels, probably the long ciliary vessels passing forwards. Retinal vessels could be traced up to the margin of the defect and were then lost; the conclusion reached was that the retina was absent over the defect of the choroid. There was no pigment either round the margin of the defect or on the base. Except for the fact that both optic discs showed a temporal crescent, no other abnormality could be seen in the fundus.

The case is of interest on account of its rarity and its resemblance at first sight to central choroidal atrophy; colobomata of the choroid frequently show pigmentation of the margins and sometimes of their bases, but the complete absence of pigment in this case is very much against a simple atrophy of the choroid, whilst the definitely punched-out appearance of the defects and their marked symmetry point to colobomata of the choroid.

E. R. GUMMERS, F.R.C.S.E., D.O.M.S.,
Ophthalmic Registrar, Bristol Royal Infirmary.

VESICULAR MOLE AND PLACENTA PRAEVIA.

June 10th I was called to attend Mrs. H., a primipara 22, for flooding. I found the uterus about one inch above the umbilicus and the os closed. She told me she had been losing on and off for the past two months and had had a severe haemorrhage the night before. Amenorrhoea had been present since the end of December. At the time of examination there was no loss. I told her to stay in bed, and subsequently made a provisional diagnosis of placenta praevia. Nothing further occurred till June 22nd, when I found the os opened sufficiently to admit the tip of the finger. On June 24th the os was further opened, and I found the placenta sentient and detached all round as far as my finger could reach. My partner, Dr. Pittard, saw her with me, and we decided to terminate the pregnancy.

The same evening, however, we were urgently sent for as there was another flooding. I found the placenta presenting the os about the size of a five-shilling piece, and easily detachable. I perforated anteriorly to evacuate the liquor, but none came. Then she had two smart haemorrhages, after pains, the second amounting to nearly a pint.

I decided to administer an anaesthetic and bring down the placenta, but was surprised to find that there was no child there. On withdrawing my hand a mass of vesicles followed, and the uterus was then easily emptied by pressure from outside. I explored the uterus and removed a few small clots remaining. I gave her 1 ccm. pituitrin extract and there was no further bleeding. The vesicular mole removed lay in an ordinary bed chamber. On the second day the temperature was raised, but it fell on the third day, and she had an excellent recovery.

The case was a marked feature, beginning six weeks before increasing in severity as time went on up to delivery. The labia minora were oedematous, but I did not test them before delivery.

The interest of the case lies in the fact that vesicular degeneration had taken place with a placenta praevia, which prevented vesicles from being evacuated.

W. H. LOWMAN, M.B., F.R.C.S.

Rebucius.

DISEASES OF THE CEREBELLUM AND OF THE STEM OF THE BRAIN.

THE recent interesting lecture upon the neo-cerebellum by Professor Winkler and the important Croonian lectures by Dr. Gordon Holmes on the clinical symptoms of cerebellar disease and their interpretation being still fresh in the minds of neurologists and many other readers, the very lucid and comprehensive work upon diseases of the cerebellum and the stem of the brain by Professor CLAUDE and Dr. LÉVY-VALENSI, which represents the latest views of the French school of neurologists, is especially welcome.

After devoting a few chapters to general considerations, the authors give a clear and comprehensive account of the macroscopic and microscopic anatomy of the cerebellum and adjacent structures, illustrated by admirable schematic diagrams and pictures. We could have wished that an account of the comparative anatomy of the cerebellum had been included and reference made to the important work of Edinger, Bolk, and others on the cerebellum of animals in relation to their mode of life.

An admirable account is next given of the physiology of the cerebellum; it is based upon experimental observations, but full references to the literature are provided. On page 30 the authors ask whether it is necessary to admit that the cerebellum plays a special part in equilibration, co-ordination, dimension of movement, and muscular tonus, as pathological conditions causing clinical manifestations appear to suggest. Although clinical manifestations speak in favour of this view, the actual tendencies are towards unification of the cerebellar functions to a simple regulative action upon muscular tonus. The disturbances of equilibrium, for example, can be explained, according to the nature of the case, by the coincidence of labyrinthine lesions (tumour), by the rupture of cerebello-labyrinthine connexions, or more simply by disturbance of the tonic cerebellar functions upon the trunk and the lower limbs (vermis). This simplification of the functions of the cerebellum is especially defended in France by André Thomas.

The authors express the opinion that cerebral connexions exist for clonic discontinuous action of muscles, and cerebellar connexions for tonic and continuous actions. This was indeed the teaching of Hughlings Jackson.

In the chapter on cerebellar somatology the authors point out that one of the difficulties, and the greatest, in its study arises from the anatomical and physiological associations of the cerebellum with the labyrinth. The recent researches of physiologists and clinicians have established certain laws which enable a differential and topographical diagnosis to be made, and in connexion therewith the beautiful researches of Babinski, of André Thomas in France, and of Gordon Holmes and Grainger Stewart in this country, and of Barany and Rothman are fully described, together with the numerous practical tests introduced by them. The value of this chapter is great, owing to its lucid descriptions of the tests and the admirable photographs and figures that illustrate them.

Chapter IV deals with anomalies, such as absence and malformation, partial agenesis, and heterotopia. In Chapter V various forms of cerebellar atrophies are discussed. The authors refer to an interesting case described by M. Claude and Mlle Loyez of crossed atrophy of the cerebellum occasioned by traumatic lesion of the internal capsule, showing probably that the atrophy resulted from the suppression of the motor stimulus. Mention is also made of an interesting case of olivo-ponto-cerebellar atrophy. This rare affection was described by Déjerine and André Thomas; subsequently a case was described by one of the authors, Professor Claude, of absolutely pure cerebellar syndrome. In connexion with this we may refer to the lecture by Professor Winkler (BRITISH MEDICAL JOURNAL, May 13th, 1922, p. 769) dealing with a case of a similar nature, which, he considered, supported the theory of a neo-cerebellum. The counterpart of the olivo-ponto-cerebellar atrophy, in which the middle cerebellar system is so markedly affected, has been described by Lejonne and L'Hermite. This was a case of olivobulbo-cerebellar atrophy in which the superior cerebellar system was affected, the middle being intact.

¹ *Maladies du Cervelet et de l'isthme de l'Encéphale*. Par Professor Henri Claude et Dr. Lévy-Valensi: Nouveau Traité de Médecine et de Thérapeutique. XXXII. Paris: J. B. Baillière et Fils. 1922. (Roy. 8vo, pp. 439; 104 figures. Paper covers, frs. 35; boards, frs. 42.50.)

The chapter on tumours of the cerebellum is very interesting; in it reference is made to the remarkable work of Gordon Holmes and Grainger Stewart. The authors agree with those English neurologists that the modifications of the fundus are slow in development, and may even be absent in cases of extracerebellar tumours. They are of the opinion that the ataxy due to frontal tumours described by Bruns is due to *action à distance* and the effects of hypertension on the eighth nerve.

Attention is drawn to the considerable literature of cerebellar lesions due to cranial injury, lesions which were rarely met with before the great war. Here again the work of Gordon Holmes is mentioned together with that of André Thomas, Marie, and Chatelet. It may be remarked that Holmes, from observations upon nearly a hundred cases of local cerebellar lesions, concludes that when the vermis is affected a disorder of bilateral acting muscles occurs, and homolateral disorders of the limbs when the lateral lobes are affected. Otherwise, his investigations do not lend support to a belief in cerebellar localization.

The effects on the cerebellum of infectious diseases and endogenous and exogenous intoxication are next considered; it is interesting to note that when the authors are discussing exogenous intoxications they attribute the reeling gait of the drunken man to the action of the alcohol on the cerebellum.

There is a useful chapter on the cerebellum in mental disease, where reference is made to the anatomical investigations of Klippel and L'Hermite, in the explanation of katatonia. Friedreich's disease and the differential diagnosis between it and Charcot-Marie's disease are fully considered. The authors next discuss the nature and diagnosis of diseases of the cerebral peduncles, pons, and the bulb.

Throughout the work full references are given at the foot of the page to the literature, and over a hundred photographs and illustrations serve to help the reader, although the descriptions of symptoms and the discussions of diagnosis are in themselves admirable for their completeness and lucidity of exposition.

This standard work is strongly recommended to all neurologists and others interested in the diseases of the nervous system.

F. W. MOTT.

DISEASES OF CHILDREN.

DR. LAWSON DICK'S book on *Rickets*² appears at a time when the etiology of the disease is under active experimental investigation and is the subject of vigorous discussion. He definitely takes a side in the controversy, maintaining that it is caused by unwholesome environment in early infancy, lack of fresh air, sunshine, and exercise, and denying that the factor of inadequate or defective diet plays any part in its origin. In building up his argument he is less concerned with what may be called clinical evidence—that is to say, individual cases of rickets in children and young animals—than with statistical data of the disease, its geographical distribution, and its history and duration. The rarity of the disease in Asia, China, and Africa and its prevalence in Europe and North America are emphasized; evidence is advanced to establish that it is uncommon in places where such conditions as prolonged lactation, the early use of farinaceous food, and a high incidence of acute alimentary disorders prevail and might be expected to favour its occurrence. There is an interesting and scholarly account of the history of the disease. The first and the classical description was given by Glisson in 1650, and the date and origin of rickets in England are assigned by him to the south-western counties at a period twenty or thirty years earlier. Dr. Dick argues that it probably first appeared in England under the late Tudor sovereigns, that it existed in the Netherlands and Northern France before this, and that the disease has not existed in Europe for more than four hundred years; these opinions are based partly on the absence of any descriptions in earlier medical treatises, mediaeval or classical, but chiefly on the absence of signs of rickets in the bones and teeth of skeletons before this period. The appearance and prevalence of the disease in Europe coincided with the transition from the agricultural and pastoral to the industrial era. At this period, without any important change in the diet of infants, there was a change from the environment of open air and freedom to that of confinement in unwholesome

conditions. Dr. Dick relates that under the Stuarts even the infants of the rich were brought up in small, unventilated bed closets, and advances contemporary evidence of the prevalence of rickets at this period. Rickets to-day is less prevalent than it has been, but it still constitutes in the opinion of the author the most important single adverse factor in the national physique and health.

The book is thus a vigorous advocacy of the view that rickets is caused by bad hygiene, and not by bad food; and the author must be praised for his collection and able presentation of much evidence of a general and very interesting kind. There is perhaps a tendency to press the argument too strongly. "The great majority of the mothers breast-feed their infants, and the great majority of these children develop rickets" (p. 9). "Yet rickets is rampant in the colliery districts, in spite of the fact that malt and cod-liver oil are freely administered to these ailing children" (p. 75). Assertions such as these cannot be accepted without full evidence.

It should be added that adequate clinical descriptions of the disease are included, and that there is a particularly valuable account of the hypoplastic changes in the permanent teeth produced by rickets. The book as a whole gives a wide and interesting survey of the subject, and is written by one who has had clinical experience of the disease and possesses a thorough acquaintance with the literature.

*The Management of the Sick Infant*³ is the somewhat vague title of a volume of over six hundred pages by Dr. Langley Porter and Dr. W. E. Carter. In their preface the authors state that they have written the book to supply the lack of "a textbook in the English language which deals exclusively with the peculiarities of disease as it occurs in infants," and especially to deal with treatment. The period of infancy is taken to cover the first two years, but the authors have included in their survey diseases which, though uncommon at this early period, do sometimes occur.

The plan of the book is curious; it consists of three distinct parts. The first deals with common and important symptoms of disease in infants, such as vomiting, diarrhoea, constipation, haemorrhage, cough, and convulsions; under each heading a catalogue of the various diseases that may cause the symptom is given, and the appropriate treatment for each is then indicated. There are certain advantages in this way of approach when symptoms, such as severe diarrhoea or a series of fits, demand in themselves special treatment; but it is apt to bring together a number of disorders which have little or no pathological relation to one another. This section also includes a chapter on nutrition, dealing with the common errors of feeding in infants and with their treatment. The second section follows the more usual classification of diseases according to the systems affected, with a regular description of pathology, symptoms, and treatment. Under the nervous system a clear and helpful account of the various types of mentally defective children will be found. There is also a chapter on infectious diseases. The third part deals with special methods of treatment and of diagnosis used in infants. It is the most concise and useful section of the book. The collection of blood intravenously from different sites; the injection of fluids and drugs by the hypodermic, intramuscular, and intravenous routes; puncture of the spinal canal, the thorax, and the abdomen; gastric lavage; the use of baths and packs; the different skin tests—these and other procedures requiring special adaptation for infants are carefully described; the directions are given in tabulated form and in many instances our understanding is greatly assisted by clear photographs. Food recipes and a formulary for drugs are provided. The book as a whole contains a great deal of accurate information, but its arrangement and presentation are faulty. The important subject of rickets is partly dealt with in the chapter on nutrition, and there are scattered references to it throughout the book; but in the index the only reference is to three prescriptions in the formulary. There is also the lack of a connected account of the normal physiology and growth of the healthy infant. The book is not well planned; and the impression of confusion and incompleteness which some of its chapters leave with the reader arises largely from this faulty planning. For this reason it cannot be recommended as a textbook for the student, but the practitioner will find in it many useful hints for treatment.

² *Rickets: A Study of Economic Conditions and their Effects on the Health of the Nation*. By J. Lawson Dick, M.D. Edin., F.R.C.S. Eng. London: William Heinemann, Ltd. 1922. (Demy 8vo, pp. xiii+483; 7 plates and other illustrations. 25s. net.)

³ *Management of the Sick Infant*. By Langley Porter, B.S., M.D., M.R.C.S. Eng., L.R.C.P. Lond., and William E. Carter, M.D. London: Henry Kimpton. 1922. (Roy. 8vo, pp. 654; 54 illustrations. 42s. net.)

After an interval of four years the eighth edition has appeared of *The Diseases of Infancy and Childhood*,⁴ prepared by Dr. EMMETT HOLT, with the co-operation of Dr. HOWLAND, of Johns Hopkins University, Baltimore. This steady appearance of new editions is the best testimony to the value of the book, which needs little further notice and commendation. It is one of the very best books on the subject in the English language, and the new issue, though showing evidence of careful revision and containing some additions, closely resembles its predecessor in general plan and text. A short account is given of encephalitis lethargica; of vitamins, in which the connexion of rickets with vitamin fat-soluble A is provisionally regarded as not proven; and of food idiosyncrasies in young infants, where the authors also take up a cautious attitude with regard to the association of infantile eczema with sensitization to food. The earlier sections of the book, dealing with infant physiology and growth, the principles of hygiene and nursery management, and the essential facts as to human and other mammalian milks, are admirable—complete in detail, and yet practical and easily followed. Indeed, on this part of his subject Dr. Holt speaks with authority.

The combined experience of the two authors is reflected in the rest of the book, in its account of the pathology, the symptoms, and the treatment of disease, is equally good, and is written first-hand from experience and from life. The clinical pictures of children suffering from disease are unusually clear and graphic. The illustrations are numerous and good; though they have been reduced in number, thirty new ones have been introduced. The volume is a little smaller than its predecessors; but with its eleven hundred pages it remains a large book, though one which gives a fairly complete survey of a subject which is wide, complicated, and important. Care has been given to the index, which is detailed and accurate.

THE TUBERCULOSIS CLINIC.

The Tuberculosis Clinic,⁵ edited by Dr. NOEL D. BARDSWELL, is a manual composed of chapters by several writers, dealing chiefly with the classification of the disease and with the management of the dispensary in town and country. It is written with the object of equipping the inexperienced tuberculosis officer with the information necessary for the adequate performance of his work. As is so frequent in books owing to a diversity of authorship, there is a lack of a unifying purpose in the ideas contributed by the various writers, which points to the absence of that close co-operation requisite for the execution of all tasks in which team work is engaged. Particularly is this noticeable in such questions as those dealing with pathological diagnosis and with treatment. Is the examination of sputum, pus, and urine to be undertaken by a pathologist or by the clinician? It is clear that the different authors tend to disagree on this point, and even the writer who is responsible for the chapter on pathological diagnosis does not seem to be very certain himself about the answer. If it be written for the pathologist we would condemn it as altogether too elementary; if, on the other hand, it be intended for the guidance of the tuberculosis officer himself there is a notable deficiency in the directions given as to the recommendation of methods, the interpretation of results, and the whole question of cytology. Unfortunately a compromise is proffered in the shape of an enumeration of the various technical procedures which may be employed by the immunologist without any definite indication as to the meaning of the results obtained. Again, with regard to treatment, opinions are obviously at variance. The writer of one section lays stress on the importance of continuing treatment at the dispensary itself, while the writer of another section would regard his duty as consisting in the supervision of the patient's treatment, leaving the actual details to be worked out by the practitioner in charge.

The chapter on clinical diagnosis is likely to prove very helpful—that part of it, at least, which deals with pulmonary tuberculosis. It is a matter of regret that the author has considered it necessary to add a description of the other forms

of tuberculosis; having quite insufficient space to deal with the multiple manifestations of this disease in glands, bones, joints, abdomen, larynx, eyes, and genito-urinary system, he has contrived to cram them all into the compass of five and a half pages—an allowance barely enough to give more than a list of the various possible lesions.

The various difficulties attending the organization of the dispensary in rural districts are well brought out, and several valuable suggestions put forward as to the ways of combating them. The most attractive part of the book is the chapter on the urban clinic, contributed by Dr. R. C. Wingfield. Singularly lucid and delightfully concise, it is obviously written by a man who is speaking from considerable experience and who has no doubt in his own mind as to the general purpose of the tuberculosis clinic and the best means of carrying it into execution. Great emphasis is laid on the distinction between the medical and the social aspects of the clinic and on the importance of close co-operation between the two sides. On this point he is very explicit. For instance, he says:

"No doctor in this world can cure or even improve the health of a consumptive workman with an invalid wife and several small children, nor can any social worker; but the two in conjunction can and have done so in many cases."

Finally two useful chapters on classification and on the keeping of reports are added. Though lacking in unity of vision the book should prove of value in virtue of the recommendations it contains from workers who are speaking from personal experience of the problems of the tuberculosis clinic.

AN ATLAS OF SYPHILIS.

The Atlas of Syphilis,⁶ by Professor L. v. ZUMMUSCH of Munich, an English edition of which has recently been published, is altogether a work of considerable artistic merit. It is really a collection of colour photographs taken direct from patients suffering from syphilitic lesions. As the work is intended primarily for students and practitioners the aim of the editor has been to reproduce the more typical and the commoner lesions of syphilis rather than rarities. This bulk of the plates, however, are of skin lesions, as these lend themselves best to such a method of reproduction. Syphilitic affections of mucous membranes—as, for example, ulceration of the palate or of the pharynx—are not within the scope of colour photographs and are missing from the Atlas, although the editor has succeeded in reproducing such conditions as gumma of the tongue and papules on the labial mucous membrane. Examples of the morbid anatomy of syphilis have also been included, and the coloured photograph of syphilitic arthritis is a particularly successful reproduction. There are also some illustrations of *Spirochaeta pallida* seen under dark-ground illumination, and by methods of staining. These plates, however, have been reproduced from water-colour paintings and not from colour photographs.

Although the limitations of coloured plates as a means of teaching must be recognized, it must be admitted that the *Atlas of Syphilis* reproduces the appearance of cutaneous syphilis better than any atlas we have previously seen. The workmanship of the plates is excellent, and the special process which Dr. Traube has employed in the colour photography has given good results.

The letterpress, for the translation of which Dr. J. SNOWMAN is responsible, is limited to a very brief description of the coloured plates. It is intended that the work should be used in conjunction with a textbook, and so used it should be of great value to anyone wishing to familiarize himself with the commoner external syphilitic lesions.

NOTES ON BOOKS.

MR. ARMITAGE's little book on *Diet and Race*⁷ contains three essays setting out evidence of an association between the diet and the anthropological characters of the races of mankind. The first gives some interesting particulars of the diets of many primitive tribes which lead the author to conclude that low stature and chronic undernutrition are causally related. The second and longest essay sustains the thesis that the intensity of pigmentation is largely determined by the racial habit in the matter of consuming salt: races taking much salt are, other things equal, fairer-skinned than races consuming

⁴ *The Diseases of Infancy and Childhood, for the use of Students and Practitioners*. By L. Emmett Holt, M.D., Sc.D., LL.D., and J. Howland. Eighth edition, fully revised. New York and London: M.V.O. M.D., F.R.C.P. London: John Bale, Sons, and Danielsson, Ltd. 1922. (Demy 8vo, pp. xix + 1127; 172 figures, 6s. net.)

⁵ *The Tuberculosis Clinic*. By Several Writers. Edited by Noel D. Bardswell, M.V.O. M.D., F.R.C.P. London: John Bale, Sons, and Danielsson, Ltd. 1922. (Demy 8vo, pp. v + 111. 6s. net.)

⁶ *Atlas of Syphilis*. By Professor L. v. Zummusch. London: J. Bale, Sons, and Danielsson, Ltd. 1922. (8½ x 12; 31 plates. 30s. net.)
⁷ *Diet and Race. Anthropological Essays*. By F. P. Armitage, M.A. London and New York: Longmans, Green, and Co. 1922. (Demy 8vo, pp. 143; 7 figures. 7s. 6d. net.)

little. The third paper deals with the mechanics of the jaw and the possible effect of diet upon the conformation of the skull. The medical reader will be of opinion that Mr. Armitage's knowledge of physiology is insufficient for the task in hand; thus, although it is quite true that we do not know very much about the chemistry of pigmentation, we know a good deal more than is to be found in Sheridan Lea's textbook. But Mr. Armitage's modest hope that "the perusal of these pages will stimulate someone to exploit completely the field I have ventured to look into" should disarm the technical critic. The literature of pigmentation is of course very technical, but Mr. Armitage might have consulted the monograph upon *Albinism* by Professor Karl Pearson, Dr. Usher, and the late Mr. Edward Nettleship, which contains much information relevant to his inquiry.

The man in the street, although his way is lighted by the flame arc, and hastened by electrical propulsion, understands less about electricity than about any other of the principal applied sciences. This is due to the fact that most of the developments in electricity during the last eighty years have been mathematical in character. The purpose of Mr. S. G. STARLING in his *Electricity** is to make the subject intelligible to the general reader without resort to mathematics, and in this he has succeeded. He contrives, in a work of modest dimensions, and in a style which never loses the interest of the theme in a mass of technicalities, to trace the development of the science from the first experiments of wondering men who rubbed a piece of amber with wool, to describe the electro-magnet and some of its applications, and to lead up from Faraday's discovery of the possibility of producing current by mechanical means to the uses of that current in the production of motive power and illumination. Then he goes on to the telegraph, the telephone, and "wireless," and after this to electrolytic processes and α rays and radio-activity. With diligent study and continual reference to the glossary of electrical terms which is appended, the reader should acquire sufficient understanding of the theory of the apparatus of which he daily makes use to be able to act helpfully in an emergency due to some electrical accident or failure. Medical electricity does not come within the author's province.

A new edition of *The Financial Times Income Tax Guide*† has lately been issued. This summary of the Income Tax Regulations and guide for taxpayers seeking a return of overpaid tax or desiring to make sure that their assessments are not incorrectly charged is clearly printed and well arranged. Undoubtedly good value is given for the price demanded. We rather doubt the advisability of endeavouring to compress into such small compass information on the excess profits duty and the corporation profits tax; the space so occupied might have been utilized for setting out more detailed instructions as to the expenses properly chargeable in computing profits and similar matters. The provisions in the Finance Act of 1922 have not been overlooked, but the author has fallen into the error of not rewriting all portions of the booklet affected; for instance, on page 19 we are told that Schedule D covers the salaries of persons employed by private traders, which is incorrect and inconsistent with the statement on page 20 that employees' assessments are transferred to Schedule E by the 1922 Finance Act.

* *Electricity: Science in the Service of Man.* By S. G. Starling, A.R.C.Sc., B.Sc., F.Inst.P. London: Longmans, Green, and Co. 1922. (Demy 8vo, pp. 253; 127 figures. 10s. 6d. net.)

† London: *The Financial Times*. 1922. (Is. net. post free 1s. 1½d.)

NOVA ET VETERA.

"BORN WITH A CAUL."

MAN is a credulous animal. Witchcraft is nearly, if not quite, obsolete in England, but many people will not light three cigarettes with one match, and the Harrow Council has soothed the apprehensions of its citizens by substituting "12a" for "13" on the Harrovian street doors. One of the most remarkable and ancient superstitions is that connected with the child's caul. It seems strange that anyone should think that a human being's future fortune could be affected by the manner in which the amnion and the foetus parted company, that the child who passed in the usual way through a rent in the membrane should be less lucky than the one who carried away part of it over his head. Yet it would be rash to conclude that this belief, which is at least 1,600 years old, is even now quite dead, for as late as 1903 a caul was offered for sale in the advertisement columns of the *Globe*, and in 1895 two cauls were advertised in the *Bazaar*, one for £5 and the other for £1. These are bargain prices as compared with those asked by the advertisers in the *Times* of

May 6th, 1814, who offered five cauls for sale: two of twin children for 35 guineas, and others for slightly lower prices—one, indeed, "very complete," being priced as low as £10.

The superstition that it is lucky to be born with or to possess a caul has been general throughout Europe. The French have a saying of a fortunate person, "Il est né coiffé." In Germany, according to Grimm, children born with a "Holm" see ghosts, spectres, and witches—a privilege of doubtful value. Similar beliefs have prevailed in Holland and Iceland. Cauls appear to have been valued by Roman lawyers in the fourth century. The possession of one of these was believed to make its owner fortunate and successful in his pleadings. At that time nothing seems to have been said of its value as a prophylactic against drowning, for which it has been most valued in this country. The belief that cauls were lucky was very prevalent in the early days of the Church, and St. Chrysostom denounced it. In *The Golden Bough* Sir James Frazer states that among some Asiatic islanders

"a child born with a caul is expected to enjoy, in later years, the gift of second sight—that is, that he will be able to see things which are hidden from common eyes such as devils and evil spirits."

In the island of Timor a fertilizing virtue is ascribed to a caul:

"It is dried and carefully kept in a box. When rice-stalks are black and the ears refuse to set, a man will take the box containing the caul and run several times round the rice-field in order that the wind may waft the genial influence of the caul over the rice."

It is worthy of note that among many primitive people very great importance is attached to the disposal of the placenta and umbilical cord. Sir James Frazer says that in some cases the placenta is carefully preserved under the house, and is believed to be a twin being of the child and the procreator of its children. It is the seat of the external soul.

The word "caul" means simply "a close-fitting cap," and as late as the beginning of the last century it was still used for a skull cap.† That the caul sometimes more resembles a hood than a cap is shown by the story quoted by Burton in his *Anatomy of Melancholy*, from one Guianerius,

"of a silly jealous fellow, that seeing his child newborn include in a caul thought sure that a Franciscan that used to come to his house was the father of it, it was so like the friar's cowl, and then upon threatened the friar to kill him."

In the north of England a caul is known as a "silly how" or "hood." "Silly" (German *selig*) means primarily "blessed" or "fortunate," and only secondarily "feeble-minded." In those parts not only is the original owner thought to be lucky, but this luck can be transferred to anyone who owns or preferably carries the caul. At the same time there is or was till recently a prevalent belief that there is a sympathetic relation between the original caul-bearer and the membrane when they are separated. Several writers in *Notes and Queries* have testified to this. By some it is believed that the caul becomes moist its absent owner is in trouble; by others, on the contrary, if it shrivels up its owner is wasting away.

A writer in *Notes and Queries* of October 12th, 1889, quotes from the *Leeds Mercury* an instructive account of what may well be the birth of a legend about a caul. At the time of the birth of a certain child the precious membrane was laid aside by the nurse for safe keeping upon a Bible, where it remained unnoticed until it was dry. It was then found to have the words "British and Foreign Bible Society" impressed upon it. There was tremendous excitement among the gossips, and despite the obvious but prosaic explanation given by the doctor in attendance, the neighbour persisted in regarding this as a miraculous occurrence and declare that the child was born to be a missionary.

In *David Copperfield* Dickens wrote:

"I was born with a caul, which was advertised for sale in newspaper at the low price of 15 guineas. . . . There was only one offer for it—£2 in cash and the balance in sherry."

Apparently Dickens meant to intimate that even in seafaring Yarmouth cauls were already discredited. A dramatized version of *David Copperfield* was produced at the Strand Theatre in 1850 under the not very attractive title, *Born with a Caul*.

The will of Sir John Offley, knight, of Madely Manor, Staffordshire, which was proved in 1568, bequeathed the caul with which he was born and which is described as containing "one jewel done all in gold enamelled" as an heirloom.

† See the description and portrait of General Mack, reprinted from the *Memoirs of Major-General Le Marchant* in the *Journal of the Royal United Service Institution*, vol. lxxvi, No. 462, May, 1921.

British Medical Journal.

SATURDAY, SEPTEMBER 23RD, 1922.

A CANADIAN MEDICAL CURRICULUM.

As was fully set forth in the Educational Number of the JOURNAL (published on September 2nd), the General Medical Council's resolutions and revised recommendations regarding the curriculum of study for entry into the medical profession take effect from the beginning of 1923. The same subject, from the point of view of the granting of its own degrees, has been occupying the consideration of the University of Toronto, the broad result being that, beginning with the session 1919-20, a six years' course is now required for every graduate. The current *Calendar* of the university affords material for comparison of the principles followed in this country with those which have actuated the Toronto authorities.

The difference in minimum duration of study—five years here and six in Toronto—is nominal and negligible, the subjects of chemistry, physics, and biology being part of the medical course at Toronto, whereas here the first and second of these must in future be passed before matriculation, and the third may be passed immediately after it. A point of importance, however, is that the minimum age of entry is on the completion of the seventeenth year both here and in Toronto, so that the earliest possible date of registration is a year later at Toronto. The graduate of that university must have completed the twenty-third year of his age, instead of the twenty-second, as with us; he must, in short, be a little more mature in outlook and experience of life before he can enter upon the practice of medicine through the Toronto portal. That is a significant sign of the general conception there of the qualifications which should be possessed by a member of the profession. When we come to note the contents of the curriculum, the conception is developed. At the end of his first year the student must pass an examination in "science and civilization and English expression." The Toronto view, in general, is well expressed in the *Calendar*, where the student "is advised to devote a certain proportion of his optional hours to the study of such subjects of general knowledge as will assist in providing him with that breadth of outlook and catholicity of interests which will enable him to enter with intelligence into the life and interests of the communities with which he may find himself associated, and to speak and write in a clear, simple and convincing manner." Again, as a preparation for general practice the student should remember that his profession will be at least as much a branch of social service as of technical scientific practice, and that upon a number of occasions in his career he will likely be called upon for advice and guidance in matters in which not only his medical skill and knowledge will be involved, but also social, ethical and economic factors, a right understanding of which will often enable his services to be much more effective"; and he is therefore to acquire some knowledge "of the leading principles of ethics and economics, including sociology." Reference to "optional hours" in the first of these quotations calls attention to a prominent feature of the Toronto curriculum. In every one of the six years there are optional subjects to be selected under the guidance of a professor appointed to act as students' adviser. The choice will depend largely on the particular field of work to which the

student is likely to devote himself, looking to his qualities and inclinations; but no attempt is made by means of optional classes in the later years of the curriculum to train students as specialists.

The Toronto University plan is very interesting and very attractive. It aims at making its medical graduates not merely doctors but men of culture. When Europe was slowly and blunderingly emerging from mediæval darkness it was very long before the practice of medicine received any appreciable benefit from the newer knowledge, yet even then some learned men endeavoured as physicians (in distinction from apothecaries) to apply scientific principles to the treatment of disease. Their learning was much more general than medical, yet they obtained some guidance by relying on observed facts of nature. In modern times, and never so much as in the present day, scientific medical research and the applications of accumulating knowledge to the prevention and treatment of disease have become so absorbing and so extensive that five or six years can be far more than fully spent without going beyond the narrowest limits of purely medical study. At the same time, it is most desirable that the modern doctor should be more than a mere doctor—that he should have a wide outlook, and know something of the humanities, in the old sense of the term. Of course, he learns much after he does enter on practice—all his life he ought to be learning. That aspect of the matter cannot be too strongly pressed. If he wishes to do justice to his work and to himself he must always be a student. The conception of a medical career must never again be that the obtaining of a qualification enables a man to settle down to earn a living on the basis of the knowledge he has acquired once and for all at college. But the present question is, What foundation of general culture should be laid by means of definite instruction? Ought it to be confined to the pre-curriculum stage, or be extended into the period of medical study? In this country the former is the method followed; in Toronto University evidently it is the latter. The system there is to some degree facilitated by the method of options, and for the rest we take the view to be that some non-medical subjects are more important to the doctor than some items in the strictly medical courses. Whether there is any difference in the matriculation standards between Toronto University and the universities in this country we do not know, but any such difference would be a relevant consideration in comparing the two schemes. It is, however, a question of the balance of advantage. The more a doctor knows about all medical subjects the better it is in whatever line he may specialize. Yet the more also he knows of science and culture outside of medicine the better it is. But a quart cannot be put into a pint pot, and life is too short and too uncertain to justify the devoting of more than a limited time to professional training. It would be interesting to know whether the Toronto curriculum was devised by the medical faculty alone or by the whole senate of the university. If the latter, then naturally the importance of the humanities would be prominent throughout the entire discussion of the scheme. On the other hand, it is just conceivable that a body like our General Medical Council, wholly medical in membership, and acquainted not only with medicine, surgery, and midwifery, but with the importance of all the special subjects taught at the schools, might tend to deal with the problem rather in a strictly professional than in a university frame of mind.

Going more into the details of the Toronto curriculum, it may be noted that the *Calendar* of the university points out that no prescribed course of study of practicable length can fit the student for all the special careers the profession of medicine offers; he is urged early in his course to make up his mind whether he intends to go into general practice, to specialize in medicine or surgery,

or to make his career in laboratory investigation and teaching, public health, or psychiatry. The six years' curriculum provides that the student may supplement his ordinary medical work by a somewhat more intensive training than is needed by all students, so as to prepare him for some particular type of medical career. A number of courses of optional study are provided. Among the subjects open to the first-year student, English history, scientific French, or scientific German is especially recommended. At the beginning of his second year it is considered a decided advantage to the student who aims at laboratory investigation, hygiene, or psychiatry in his career to make his choice, and upon it the optional subjects for the second and subsequent years largely turn. The student who is preparing himself for a specialist career in medicine or surgery is recommended to equip himself as thoroughly as possible in the introductory medical sciences, and it is suggested that in his second and third years the bulk of his optional studies should be chosen from subjects of this kind; he is, however, also required to select during both years one course in a subject such as history, economics, philosophy, or psychology. In like manner those aiming at careers in public health and laboratory investigation are advised to be guided by the requirements of the subject in which they desire to work, but they are reminded that in all paths of laboratory research the importance of mathematics is rapidly growing. Students attaining a certain standard in the courses of the first three years are allowed to continue taking optional subjects during their fourth, fifth, and sixth years, while others are required during their fourth year to take "review courses" in certain of the fundamental medical sciences, and, in the fifth and sixth years, in certain subjects of the preceding years. Assignment to these groups is made by a special committee of the Faculty of Medicine, which also decides upon the courses to be reviewed and allots the students to each. A student earning a good report during his fourth or his fifth year may be promoted from the "review group" to the "optional group"; but, as already noted, emphasis is laid on the principle that no attempt is to be made in the optional classes of the later years to train students as specialists. Thus, such subjects as laryngology, ophthalmology, and radiology may not be chosen at that stage, since it is thought unsound to train men to be specialists in these fields until they have thoroughly rounded off their medical or surgical education and served a year as a resident in hospital—an opinion with which there will be general agreement. On the other hand, students who have definitely decided that their future career lies in one of the specialties may, during the time set apart for optional study, take courses in the pre-medical or fundamental sciences upon which these specialties depend—for example, in those parts of physics and physiology that deal with optics, acoustics, or radiology.

The Toronto scheme is just what might be expected from a young and vigorous country with a fresh and open outlook. Its developments and results cannot but be watched with appreciative sympathy by all who have at heart the broad interests of the advancement of medical and general learning.

"BAYER 205."

A CURIOUS illustration of the German desire, not unnatural in itself, to regain the tropical colonies lost by the folly of the rulers of the German Empire, is afforded by a discussion which took place at a meeting of the German Association of Tropical Medicine at Hamburg. We have not seen a full report of the meeting, but the *Times* correspondent in Hamburg reports that one of the

speakers said that "Bayer 205 is the key to tropical Africa, and consequently the key to all the colonies. The German Government must, therefore, be required to safeguard this discovery for Germany. Its value is such that any privilege of a share in it granted to other nations must be made conditional upon the restoration to Germany of her colonial empire." Some account of the drug manufactured by the Bayerische Farbwerke and provisionally named "205" was given in our issue of May 20th (p. 807), when we quoted Dr. H. H. Dale's opinion that it was a remarkable curative agent in trypanosome infections. A general account of the probable chemical relationship of "205" is given by Dr. King in the sixth Annual Report of the Society of Chemical Industry (1921).

In 1904 Ehrlich and Staig discovered the trypanocidal action of trypan red, a compound formed by combining one molecule of tetrazotized benzidine-mono-sulphonic acid with two molecules of sodium naphthylamine disulphonate. In 1906 Mesnil and Nicolle¹ investigated a series of dyes containing amino-naphthalene-sulphonic acid and found that the most active trypanocidal agent was a dye prepared by the Bayer firm. Little notice was taken of this work, and the discovery of salvarsan diverted attention from the trypanocidal dyes to the organic arsenic compounds. The Bayer firm, however, continued to investigate the trypanocidal dyes and discovered that compounds of this type which were not dyes might still be active trypanocidal agents. They took out a large number of patents, and the type of compound to which the firm has paid special attention is represented by the following formula:

A number of substances of this type have been found to be very active trypanocides, and probably Bayer 205 is a derivative of this type. Bayer 205 is a white powder, freely soluble in water, forming a colourless solution, which can be sterilized. Animal experiments² have shown that it is an extraordinarily powerful trypanocidal agent, and that a single dose of it will produce immunity to trypanosomes for several weeks or even months. Mayer and Zeiss, for instance, found it cured infection with five different kinds of trypanosomes, that the ratio between the minimal lethal and minimal curative doses was as high as 167 to 1, and that a single dose of 3 mg. rendered a mouse immune to trypanosomes for three months. Recurrences were found to be extremely rare when infected mice were given a single curative dose of the drug.

The various workers have reported curative effects on trypanosomal infections in mice, rats, guinea-pigs, rabbits, dogs, and horses. In England Wenyon³ found that the drug was an extraordinarily effective trypanocidal agent. A brilliant success has been reported in a case of sleeping sickness.⁴ The case was of a year's standing, and had been treated unsuccessfully with arsenic, antimony, and emetine. Four doses of "205," making a total of 3.5 grams, were given. A few hours after the first dose the fever disappeared, and a complete cure appears to have been produced, for four months later there were no signs of recurrence of the disease.

The drug therefore appears to be a trypanocidal remedy of the first importance, and the fact that a

single dose confers prolonged immunity to trypanosomes suggests that it will be of the greatest value as a prophylactic. A commission of German doctors is now in Rhodesia testing the drug, and our knowledge as to its action in man will soon be much more extensive. The discovery of "205" promises to mark a great advance in tropical medicine, but it is a remarkable fact that England should be dependent on Germany for this advance in tropical medicine, for at present Germany is not a single colony, while England has the largest tropical empire in the world. It is not a position of which we have any reason to be proud, but its cause is simple. Germany appreciates the value of pharmacological research and we do not.

THE INTERNATIONAL CONTROL OF DANGEROUS DRUGS.

AMONG those who seek to reduce the supply of drugs of addiction, such as opium, morphine, and cocaine, to something approaching the amount required for legitimate purposes, the news of the destruction by fire of the great Darmstadt chemical works of Merck, last Friday, will be read with equanimity. While the League of Nations has so far found it difficult to determine with precision the amounts of these drugs required by different countries for medical and scientific purposes, it appears to be satisfied, as is the man in the street, that the supply is grossly in excess of legitimate demand, and that enormous quantities pass into illicit hands and are put to vile purposes. In the *BRITISH MEDICAL JOURNAL* of August 19th we draw attention to the alarming increase of this sinister traffic in Paris and other parts of France and to the inadequacy of the fines imposed on the agents detected in carrying on this lucrative trade. Our own Home Office is similarly alive to the fact that the penalties imposed under the Dangerous Drugs Act of 1920 are insufficiently deterrent, and it is stated that a mending bill has been drafted which will authorize twelve months' imprisonment with hard labour for a first offence.

In these columns for the last decade we have uniformly urged the need for international control, not only of the distribution, but of the production of these perilous habit-forming drugs. So long as the actual growth of 10 *Papaver somniferum* and the *Erythroxylon coca* is unlimited and unsupervised the market will be liable to be flooded with their alkaloids and preparations and the excess of supply over legitimate demand will find its way into unlawful hands and be prostituted to vicious uses. In the memorandum compiled by the Advisory Commission of the League of Nations, based on the replies to the questionnaire which they issued to the various Powers, the information vouchsafed as to the manufacture, import, and export of the drugs in question is very imperfect. In regard to cocaine the only countries in which the manufacture of that alkaloid is acknowledged are Japan and Switzerland. Germany and the United States had furnished no statistics. Great Britain is stated to import largely from Peru and to export chiefly to France and the Netherlands. Switzerland manufactured 732 kg. of cocaine in 1921 and received considerable imports from Germany and France. Japan manufactured 4,100 kg. of cocaine in 1920, and in the same year imported 3,500 kg. chiefly from the United States, but also from Switzerland, France, and Great Britain. "Enormous quantities of opium," it is stated, "largely of European and American origin, have been reaching China from Japan during the last few years." A recent reply in the Commons stated that 643,985 oz. of morphine were manufactured in 1920 in England and some 322,484 oz. of morphine and opium were exported in addition to exports by post.

All this serves to show that there is urgent need for the universal application of the International Opium Convention of 1912. That instrument was admittedly less stringent than was desired, largely to meet the objections raised by Germany, but its effective enforcement would do much towards restricting the drug traffic to legitimate channels. It is satisfactory to learn from Geneva that Switzerland is at last about to ratify the Convention, and a resolution has been adopted having for its object the refusal of producing countries to license exports of these drugs to countries which are not themselves enforcing the restrictions contemplated in the Convention.

THE LEGIBILITY OF PRINTED MATTER.

THE ever-increasing use of printed matter under all conditions of natural and artificial illumination makes the legibility of the print a matter of high importance. The comfort of the reader is involved, possibly even the integrity of the sight of school children and students, and there is the further consideration that illegible print may be misread. Mr. L. A. Legros has prepared a paper on this subject for the information of the Committee on Type Faces.¹ The committee is concerned primarily with government publications, but the information is of value at large. Mr. Legros's note extends to fifteen folio pages, and the type used is of the most beautiful and perfect kind; yet despite its fine count of type the document is not comfortable to read. The printer has transgressed the first two rules of legibility: that the line should be of comfortable length, and that one line should be sufficiently separated from the succeeding. The lines of print are $6\frac{1}{2}$ inches wide, instead of the usual comfortable $4\frac{1}{2}$ inches of the textbook, and the descending tails of the letters of the upper line are only removed from the ascending limbs of the lower line by a fraction of a millimetre. The consequence is that the page appears as a general grey mass, and the task of following the lines in reading is so difficult as to make the appreciation of the meaning of the printed statements uncertain and perplexing. Strangely enough the two cardinal features of good print—reasonable length of line and the judicious use of "leads" between the lines—are each dealt with by the author in his paper, and an example to show the good effect of leading is given. Having noted this blemish we may say that the matter of the paper is an exceptionally careful statement of the characters of the several fonts of type in common use, and their effect on legibility. In his analysis the author employs as many categories as require paragraphs from *a* to *w*; but not one of them is redundant. There are some fifty different varieties of fonts, without considering "fancy faces" or scripts, and the author's endeavour has been to discover the defects of the chief of these. Certain letters hinder legibility. The small "i" is one of these; in certain combinations it goes to form words in which the dot causes confusion—for example, "toil" may be mistaken for "toll"; other words are clearer for the dot of the "i"—for example, "imminent." In former days a change for the better was the suppression of the long f-shaped "s" ordinarily used at the beginning and in the middle of words. This change was made experimentally in Bell's edition of *Shakespeare*, 1787. Mr. Legros notes that the short "s" was rapidly adopted both in this country and on the Continent, but that the Oxford University Press did not make the change till 1824, and we might add that Dr. John Brown's *Horae Sub-ecivae* published in 1853 was printed throughout in the old way. Not only did the change increase legibility, but it reduced the number of types in the printer's case. The relative thickness of vertical and horizontal stroke is of importance. If the vertical stroke be much exaggerated, as is found in some French printing, legibility is impaired; again, overfiness of the horizontal line induces rapid wear of the type and loss of legibility.

¹ A Note on the Legibility of Printed Matter prepared for the Information of the Committee on Type Faces. By Lucien Alphonse Legros, O.B.E., M.Inst.C.E. London: H.M. Stationery Office, 1922. 1s. 6d. net.

Similarity between pairs of characters leads to confusion. The use of the serif (the fine cross-stroke at the top and bottom of a letter—a relic of the old penman's work) is carefully discussed. Plain characters without serifs are often used for display purposes, and for that reason some have been led to suppose that this gives greater legibility. The sans-serif letter strikes the eye, but is unpleasant in page form, and there is actually a certain loss of legibility when the serif is absent; thus the dotted "i" with the serif is more readily distinguishable from the "1" than when there are no serifs on either. Dissimilarity of form is more important in figures: "3" and "5," "5" and "6" are very readily confused, as the users of a telephone directory know only too well. Much care has been expended in the past in deciding what is the best form of type, and the author agrees that the "modern" style is the best, and he confirms the observations of Babbage, who in the preface to his *Tables of Logarithms* of 1827 states that "the clearness or facility of reading does not depend on the size of the type alone, but on the proportion of the type to the interval between the lines," and "figures of the same, or nearly the same, height are preferable to those in which some of the digits rise above and others fall below the line, because they interfere with the space between the lines." The author gives two settings of a table from Bradshaw, one in modern, the other in old style figures, and the modern with its even row of figures is distinctly the more legible. The quality of the paper used and its colour and light-reflecting capacity are discussed; the colour of the ink and certain points in illumination are noted. Mr. Legros's pamphlet is of much interest, and will be of particular value to those engaged in editing and publishing; but to the general reader the report of the British Association Committee dealing with the print of school books will be the more useful.

AUTOGENOUS VACCINES.

In an article based on much practical experience Parisot and Simonin¹ of Nancy review the present position of autogenous vaccines, and specially consider the reasons why this form of treatment, though logically the correct one, has not been crowned with the success that might have been anticipated. Thus it is mainly in chronic staphylococcal infections that good results have been obtained, and even these are not constant, and are often less satisfactory than those given in response to stock vaccines; then, again, most striking cures have followed the almost haphazard employment of vaccines, sometimes even composed of micro-organisms other than those responsible for the disease. It has therefore been thought that it is unnecessary to take the time and trouble involved in the preparation of an autogenous vaccine when almost any vaccine will give equally good results. The reasons for this erroneous opinion are fully considered; as P. Delbet, Beauvy, and Girode pointed out in 1914 in connexion with the vaccine treatment of local surgical lesions, two very different effects may follow the injection of a vaccine: there is an immediate non-specific reaction, due to colloidoclastic or protein shock, which accounts for the remarkable successes of vaccines in some acute infections; and secondly, a delayed reaction due to the specific action of the microbes contained in the vaccine. It is therefore important to distinguish between bacterial protein shock and vaccine treatment, and to refer correctly to each of these factors the good and bad effects that may occur after the injection of a vaccine. The mistakes and considerable difficulties in the technique of the preparation and administration of autogenous vaccines have been responsible for much of the failure of autogenous vaccines. Parisot and Simonin, therefore, after describing the details of making an autogenous vaccine, indicate the fallacies that may arise, such as failure to cultivate the responsible micro-organism from the use of an unsuitable medium, the difficulty of choice, and the changing character of the microbes in mixed infections, and draw attention to the importance of avoiding too high a

temperature in sterilizing the cultures, and to the deterioration of vaccines on keeping. The administration of the vaccine demands meticulous care and a close watch over the reactions of the patient, so as to give the proper doses at the appropriate intervals and to suspend further treatment when contraindications appear. If vaccines are given without this care serious and even grave accidents may occur; among these is protein shock, which, though it may be beneficial, is not part of, or necessarily favourable in, vaccine therapy. It is therefore advisable that the vaccine should consist of carefully washed micro-organisms, thus excluding the complex products of the culture medium. An excessive reaction, especially at the site of the injection, where considerable increase in the inflammation and swelling occurs, is often due to a transient state of diminished resistance, corresponding to Sir Almroth Wright's negative phase; in these circumstances another injection of vaccine, if given prematurely, may induce severe symptoms, and, although the vaccine is perfectly sterile, give rise to a fixation abscess at the site of injection. On the other hand, a certain amount of increased activity and exudation in the infected focus, not only at the onset of treatment, but also after several injections have been well borne, is a favourable sign. Thus in chronic glenoid and pulmonary suppuration the first evidence of improvement may be ushered in by increased secretion of mucus, and in cutaneous staphylococcal infections there may, after a number of doses of an autogenous vaccine, be a sudden outburst of small pustules around the original focus, which rapidly disappear and are followed by improvement. Sometimes the fourth or fifth dose of the vaccine is followed by phlegmonous infiltration without fever around the site of the injection; this is Arthus's phenomenon due to local anaphylaxis. The authors are definitely of opinion that except in those that run a rapid course all infectious, acute or chronic, local or generalized, can be benefited by autogenous vaccine treatment.

MEDICAL EDUCATION IN THE UNITED STATES: TWENTY-ONE YEARS' PROGRESS.

The Educational Number of the *Journal of the American Medical Association* (published on August 19th) contains the usual statistics of medical education in the United States; also a leading article concisely reviewing the progress made during the twenty-one years that have passed since our contemporary first published these tables. It was in 1901 that the American Medical Association opened its campaign for the bettering of medical education in the United States. Many of the 159 medical colleges whose names appeared in the first list were known to be joint-stock corporations, conducted largely for the profit of their owners. At that time (the *Journal* says) "no one, in fact, knew just how serious conditions in the medical schools actually were. Sectarian medicine was at its zenith, with 22 homoeopathic and 10 eclectic colleges." In order to centralize the efforts towards reform a permanent committee of the Association—the Council on Medical Education—was set up in 1904, and one of its earliest acts was to take over the business of collecting and tabulating statistics relating to medical education. When the Council made its first tour of inspection in 1906 the United States had more medical schools than all the rest of the world put together, and, with a few notable exceptions, the standard of general and professional education in American medical schools was much lower than that in Europe. The task of discouraging the worse kind of school and stimulating the better went on steadily from year to year. Side by side with this a policy of amalgamation was urged upon locally competing institutions. By 1917 great progress had been made; the total number of schools had fallen to 95, and—more important still—the number of higher grade schools had grown from 4 to 86. There are now 81 medical schools in the United States, of which 74 require of their students before admission "two or more years of college work." During the period under review the total number of medical students has diminished by something like 40 per cent., while the proportion of students in well-equipped medical colleges

¹ Parisot, J., et Simonin, P.: *Rev. de méd.*, Paris, 1922, xxxix, 392-423.

has grown from 3.9 per cent. of the whole to 96.1 per cent. Moreover, of last year's total of 2,529 medical graduates, 1,455 had also obtained degrees in arts or science. This remarkable progress in bringing medical education throughout the United States into line with the standards laid down in other leading countries must be looked upon as one of the most important achievements of the American Medical Association.

NATURAL SCIENCE AND THE CAMERA.

THE Royal Photographic Society of Great Britain is holding its sixty-seventh annual exhibition at the galleries of the society, 35, Russell Square, W.C., from September 18th to October 28th. During the period of the exhibition lantern lectures will be given every Tuesday and Friday at 8 p.m. The photographs are grouped under various sections. In the natural history section there are many interesting pictures of birds and animals photographed in their natural haunts. Thus Mr. M. Maxwell snappd an African wild bull elephant at the distance of eight yards, probably the closest range at which this has ever been done. He also exhibits a photograph of giraffes at full gallop, travelling about thirty miles an hour. Other pictures show birds feeding their young or nesting, a meadow pipit feeding a young cuckoo, a jackdaw with an insect flying to the food at the bird's feet, and many plants, moths, and butterflies. The medal in this section is awarded to Mr. Ralph Chislett for a photograph of variations in the plumage of the Arctic skua. The section of pictorial photography contains numerous artistic productions, many of which approach in their effect the art of painting, and suggest that photography stands to this art very much in the same position as the mechanical piano-player stands to music. Some good portraits are shown, among them being those of the Archbishop of York and of the American divine who is said to address each week (in paragraphs of italic type) a congregation of thirteen million syndicated newspaper readers. The scientific section contains work of more interest to the medical man, although the purely medical productions are not very numerous. Some thirty or forty radiographs are shown, and in this department Mr. A. O. Forder wins the medal with a picture of a sarcoma of the femur. A lateral view of a head shows a piece of shell in the sphenoidal sinus; and this radiograph, together with a further series, displays the merits of the Bucky-Potter diaphragm. Amongst the radiographic negatives shown by Mr. N. E. Lubosiez is one of a fish that had swallowed a whole; both the thick and thin portions of the fish are well shown, and the details of the whelk's shell are very clear. Dr. G. H. Rodman shows several series of photomicrographs of animal and plant hairs, of the under surface of the leaf of the goosefoot, and of a horizontal section of the human scalp. The astronomical and aerial prints, many of them contributed by the Royal Observatory, the Dominion Astrophysical Observatory, and the Mount Wilson Observatory, are interesting. This section also contains examples of technical applications of photography; for instance, a Russian internal passport, which had been fraudulently used by no less than four persons; photographs from aeroplanes; pictures of bullets perforating plaster-of-Paris partitions or soap bubbles. Two cabinets of colour transparencies containing a number of slides illustrating the application of the autochrome process to stereoscopic work are very attractive. The exhibition is open daily, except on Sunday, from 11 a.m. to 9 p.m. Admission is free.

THE ADVANCEMENT OF SCIENCE, 1922.

WITH customary promptness the addresses delivered at the ninetieth annual meeting of the British Association at Hull, which closed on September 13th, have been issued in book form with an orange-coloured paper cover, under the general heading, *The Advancement of Science, 1922*.¹ When the first meeting of the Association took place at York in 1831 printing and publishing methods were more leisurely, we believe. The volume opens with the full text of Sir Charles Sherrington's

inaugural presidential address to the Association on "Some aspects of animal mechanism," of which an abstract appeared in our issue of September 9th (p. 485). This is followed by the text of the addresses given by the presidents of the thirteen Sections, arranged in the alphabetical order laid down in the programme of the meeting. The names of the Sections and their presidents and the titles of the addresses are as follows:—A. Mathematics and Physics: Professor G. H. Hardy, "The theory of numbers." B. Chemistry: Principal J. C. Irvine, Part I, "The organization of research"; Part II, "Some research problems in the carbohydrates." C. Geology: Professor P. F. Kendall, "The physiology of the coal swamps." D. Zoology: Dr. E. J. Allen, "The progression of life in the sea." E. Geography: Dr. Marion Newbigin, "Human geography: first principles and some applications." F. Economic Science and Statistics: Professor F. Y. Edgeworth, "Equal pay to men and women for equal work." G. Engineering: Professor T. Hudson Beare, "Railway problems of Australia." H. Anthropology: Mr. H. J. E. Peake, "The study of man." I. Physiology: Professor E. P. Catbearth, "The efficiency of man and the factors which influence it" (an abstract appeared in our last issue at p. 524). J. Psychology: Dr. C. S. Myers, "The influence of the late W. H. R. Rivers (President-elect of this Section) on the development of psychology in Great Britain." K. Botany: Professor H. H. Dixon, "Transport of organic substances in plants." L. Educational Science: Sir Richard Gregory, "Educational and school science." M. Agriculture: Lord Bledisloe, "The proper position of the landowner in relation to the agricultural industry." The general reader, taking modest sips in this symposium of science, would perhaps feel more at his ease if the pages of the volume were numbered consecutively.

INDUSTRIAL STATISTICS AND HEALTH.

THE members of the third annual Industrial Welfare Conference, held at Balliol College, Oxford, were addressed, on September 18th, by Dr. H. M. Vernon, who has carried out many investigations for the Industrial Fatigue Board. His subject was the importance of keeping records and statistics. He pointed out that a system of efficient records and statistics was an integral part in the new ideas of industrial management which were to-day steadily gaining ground. The elimination of waste in industrial establishments was bound to prove eventually of benefit to all concerned, and those responsible for the welfare side of large firms had opportunities for collecting valuable statistical information which no other persons attached to a factory possessed. These particulars were, however, often wasted because welfare supervisors failed to recognize the importance of keeping the requisite records. In regard to the question of labour turnover there was good reason to believe that this amounted to as much as 100 per cent. in a year. This meant a huge loss to the employers, who had the expense of training new workers, and also to the employees, who earned low wages while they were on a new job. A good knowledge of the degree of ill health in the workers and its variations could be obtained by keeping "lost time" records, especially if the time lost from sickness was separated from that due to other unavoidable causes. Accidents and injuries formed one of the chief causes of lost time; hence an accurate record of all accidents treated should be kept and should be examined statistically. The records might show that some accidents were especially frequent among workers on some particular type of machine or process, or they might show a rise brought on by fatigue during overtime work. Again, it was well known that inexperienced workers were peculiarly liable to accidents unless special precautions were taken. The effects of an accident prevention campaign should always be tested statistically. It was important also to determine whether any given workshop conditions favoured the maximum degree of health and efficiency in the workers. Dr. Vernon held that the proper person to do this was the supervisor, by keeping exact records of the temperature of the workshops and of the degree of ventilation.

NAVAL MEDICAL WAR MEMORIALS.

The memorial tablet designed for the Royal Naval Hospital at Plymouth, commemorating the names of those naval medical officers and members of the nursing staff who lost their lives in the war, will be unveiled on Wednesday, October 4th, at 3 p.m. As already announced in these columns, a tablet was unveiled at the Royal Naval Hospital, Haslar, on August 17th, and a similar tablet will be erected at the Royal Naval Hospital at Chatham at a later date, which will be notified. The Medical Director-General, R.N., requests us to state that the relatives and friends of the fallen and all others who may be interested are invited to attend the unveiling ceremony at the Royal Naval Hospital, Plymouth, or at Chatham, whichever may be more convenient for them.

The Royal National Orthopaedic Hospital (Great Portland Street) has established a country branch hospital at Brockley Hill, Stanmore, in the premises formerly known as the Mary Wardell Convalescent Home and used during the war as an auxiliary military hospital. The object of the new country branch is to give the benefits of open-air treatment and heliotherapy to patients suffering from deformities, by far the greater number of these being children. In most cases the whole of the treatment, including operation, is carried out there. On September 21st the Earl of Denbigh, Chairman of the Royal National Orthopaedic Hospital, received a party of visitors at the country branch, and gave them an opportunity of inspecting the house and grounds and the methods of treatment.

The report for 1921-22 of the Insurance Acts Committee is printed in full in the SUPPLEMENT this week. It will be presented formally to the annual conference of representatives of Local Medical and Panel Committees to be held in the Central Hall, Westminster, at 10 a.m. on Friday, October 20th.

THE JOHN ELLIOTT MEMORIAL LABORATORY.

OPENING CEREMONY AT CHESTER ROYAL INFIRMARY.

The John Elliott Memorial Pathological and Bacteriological Laboratory at the Chester Royal Infirmary has been equipped by public subscription in memory of the late John Elliott, M.D., F.R.C.P., who was honorary physician to that institution from 1835 to 1921 and one of the leading consultants in the county.

The laboratory was opened on the afternoon of September 16th by Sir Humphry Rolleston, K.C.B., M.D., D.C.L., LL.D., President of the Royal College of Physicians of London and Emeritus Physician to St. George's Hospital. On arrival at the Infirmary Sir Humphry Rolleston was met by the chairman of the board (Mr. E. M. Sneyd Kymerley) and members of the honorary medical staff, and was conducted to the laboratory. Among the subscribers to the memorial present were the Bishop of Chester (the Right Rev. Luke Paget, D.D.), Dr. Willoughby Gardner of Shrewsbury, and Mr. G. P. Newbolt of Liverpool. Tea was served in an adjoining ward before the opening ceremony.

Sir Humphry Rolleston's Address.

The title of Sir Humphry Rolleston's address was "The clinical laboratory in the modern hospital." He began by remarking on the appropriateness of perpetuating the memory of a physician such as John Elliott by the addition of a pathological and bacteriological laboratory to the institution, on behalf of which he did yeoman service for twenty-six years. This modern laboratory corresponded well with the operating theatre recently erected as a tribute to the late James Taylor, for forty years a mainstay and ornament of the surgical staff of the infirmary. Originally opened in 1756, and much extended within the last few years, the Chester Royal Infirmary had a proud record of work and workers in the past.

But the modern developments of medicine entailed fresh methods, so that for the efficiency of a present-day hospital a well equipped and staffed laboratory was, like a radiological department, as integral a part as the dispensary and theatre. It was no doubt true that when any new phase or fashion appeared a danger arose of rushing to extremes. Before the era of bacteriology and clinical laboratories the medical man

had to depend entirely on his own powers of observation, which were therefore cultivated to a high pitch of excellence, and clinical instinct—the subconscious judgement born of years of thoughtful experience—was a great asset to the medical practitioners of all time, of the present no less than of the past. The inestimable value of the laboratory, with its rapid decision of clinically doubtful diagnoses, was now established beyond question; but it must be admitted that some who had grown up with it might be tempted to rely solely on its verdict, and so to save themselves the trouble of investigating the patient. In this way fallacies and mistakes might arise, for the old adage that the patient and not the disease must be treated should not be forgotten. Against the danger of neglecting investigation of symptoms Sir James Mackenzie had uttered many wise warnings, and was setting an example in his Institute for Clinical Research at St. Andrews. The clinical laboratory, while an essential part of a complete hospital, must be closely co-ordinated with the wards, for only by their intimate association could the best results be obtained.

The laboratory met a large and ever-growing demand from the wards and out-patient rooms, and should therefore be competent to deal with all branches of pathology. How extensively this subject had grown, and into how many special branches pathology had become differentiated, was shown by the staffing of the laboratories at the larger medical schools; in fact one man could not satisfactorily cover the ground of morbid anatomy and histology, bacteriology, serology, biochemistry, clinical and experimental pathology, any more than a clinician could be thoroughly efficient in all the specialties of medicine. In hospitals without a medical school the conditions were rather different and the demands less; yet they were so considerable that they should be met by the appointment of an adequately salaried full-time director, with co-workers (one of whom should be a biochemist) and trained laboratory attendants. The other workers, except perhaps the biochemist, would be part-timers, and might be junior members of the hospital staff, for the experience thus gained would greatly increase their professional efficiency, and their presence would ensure continuous active correlation and sympathy between the wards and the laboratory.

Sir Humphry Rolleston then summarized the value of such a laboratory as this. The clinical laboratory was an advantage to the community by providing means for early detection of the nature of infections, and so preventing the spread of disease. It was of value to the individual patient by aiding diagnosis and checking the administration of modern methods of treatment. From the point of view of the medical profession such laboratories formed a centre of medical work and activity. Without this assistance a medical man in his fight against disease was like a pugilist with one arm tied behind his back. The laboratory and hospital gave him opportunities for utilizing the methods he learnt as a student and for acquiring knowledge of the progress of medicine. Deprived of this the medical man must deteriorate in value and his patients suffer accordingly. Complete co-ordination of the medical profession for the prevention of disease required a close association of the laboratories of towns and districts with the local hospitals. In every direction internal medicine depended on laboratory assistance. The surgeon, too, depended on the laboratory for aid in diagnosis and prognosis, for guidance in dealing with the problem when to operate and when to hold his hand, and for many points in the treatment of his cases. The laboratory formed a centre of research to which the profession looked for additions to medical knowledge. The expenses of the laboratory should be regarded as an insurance against epidemic outbreaks of disease both outside and inside the hospital, and so as an essential economy.

In conclusion, Sir Humphry Rolleston gave a brief sketch of Dr. Elliott's career, remarking that the tribute paid to his memory that day was one that John Elliott would have appreciated most highly. He recalled that Elliott and he entered as students at St. Bartholomew's Hospital on the same day.

"Not only was he exceptionally able, but he had the faculty—not always found with such intellectual gifts—of doing everything to which he turned his hand with the might that ensured success. The field of his activities was wide both in the strictly professional subjects and in science; a first-class general physician. He had a well-equipped laboratory of his own for the elucidation of his cases, thus realizing the ideal of present-day medicine in the investigation of morbid function; he was much interested in radiology, played an active part in the treatment of venereal disease, and, as recently as 1921, formulated precautions necessary

in the au. His work for the Infirmary as a physician's duties, for he was and execution of the important additions and improvements of ten years ago."

The vote of thanks to Sir Humphry Rolleston was proposed by Dr. J. G. Taylor, senior physician, and seconded by Mr. W. H. Dobie, consulting surgeon to the Infirmary. After the address the laboratory and the rest of the Infirmary were open for inspection. The newly appointed honorary pathologist and assistant physician to the institution is Dr. W. H. Grace, recently of Guy's Hospital.

THE HEALTH OF LONDON IN 1921.

THE annual report on public health to the London County Council, by Dr. W. H. Hamer, has recently been issued, and keeps up to the high standard which this long series of reports has attained. In contrast with 1916, "in which, in a literal and perhaps in a metaphorical sense also, more water than ever before known flowed under London Bridge," 1921 was a year of excessive drought, and June was actually the driest month ever known in the London area. In other respects last year was exceptional—for example, while unemployment had risen to 10 per cent. by the end of March, the coal strike then began, and by the end of June unemployment reached 23 per cent., an unprecedented figure.

Vital Statistics.

The population of the County of London at the census of June, 1921, was 4,483,249, or 33,436 less than at the census of 1911. The census showed that the decentralization of the population, which began some twenty or thirty years ago, still continues, and in the principal areas in which buildings have been replaced by commercial premises—the City of London, Holborn, Finsbury, Stepney, Westminster, and St. Marylebone—there was a decrease in population of over 87,000 between 1911 and 1921, about the same number as in the previous decennium. The approximate marriage rate was 19.5 per 1,000 of population, which was only slightly above the average of the last seventy years. There were 99,839 births, equal to a rate of 22.1 per 1,000 of population, which showed a substantial decline upon that of the preceding year, and was below the level to which it had fallen just before the war. The greatest decrease in the births as compared with the previous year occurred in the poorer populations, varying from 22 per cent. in Bethnal Green to 12 per cent. in Stoke Newington. The deaths numbered 56,259, the mortality per 1,000 living being 12.5, as compared with 12.6 in 1920; this is the lowest death rate recorded in London. With regard to the death rate, it may be observed that although the population has remained practically stationary during the past twenty years so far as the actual number is concerned, its constitution has undergone considerable change. London attracts young adults of both sexes, and owing to the changing constitution of its population the death rate does not measure the risk of life in London. About 70 per cent. of the population of London in 1911 were born in the country—that is to say, about one and a half millions were immigrants. The infant mortality was 81 per 1,000 births, as compared with 76 and 85 in 1920 and 1919 respectively. With the striking exception of diarrhoea, there was a decline in the mortality from most of the principal causes of infant deaths. Only two cases of small-pox occurred in London during 1921, neither of which proved fatal.

Scarlet Fever, Diphtheria, and Measles.

The deaths from scarlet fever and diphtheria were more numerous in 1921 than in previous years owing to the exceptionally high prevalence of these diseases. There were 32,738 cases of scarlet fever in London during the year, as compared with 22,705 in the preceding year, and the deaths numbered 92. The number of cases occurring during the first quarter of the year was very much in excess of the average for the quarter. The number of cases of diphtheria notified was 6,319, as compared with 13,780 in 1920; the deaths during the year were 1,150, the corresponding figure for 1920 being 1,023. The number of cases of diphtheria in London last year exceeded that in any other year since 1890, when notification of the disease became compulsory. The deaths from cases numbered 244, as compared with 1,016 in 1920. The mortality was 0.05 per 1,000 living, the lowest rate recorded in London.

No. 2168. P. S. King and Son, Ltd., or through any bookseller. 2s. 6d.

Diarrhoea and Enteritis.

There were 2,152 deaths among children under 2 years of age from diarrhoea and enteritis, giving a mortality per 1,000 births of 21.55; this rate is in excess of that for the four preceding years, but a trifle below the average for the ten years 1911-20. In view of the high average temperature of the summer the mortality from infantile diarrhoea was, in fact, remarkably low.

On investigating the figures for the thirty-eight years up to 1914 the calculated deaths are (Dr. Hamer states) in very close agreement with the numbers recorded; this agreement is indeed remarkable when regard is had to changes in classification which occurred in the course of the period, more especially late in the nineties. In 1914 and subsequent years there is a remarkable difference between the actual and estimated mortality, and as this takes in the whole of the war period the probability that the conditions brought about by the war have been responsible for the reduced mortality at once suggests itself. There is, however, some indication that the change which appears at first sight to have occurred abruptly in 1914 is really foreshadowed some years earlier. Up to 1905 the actual deaths are sometimes below and sometimes above the number calculated from the temperature; but after 1905, with the exception of 1913, the calculated deaths always exceed the actual number, and the excess in 1921 (a wet summer) was actually greater than in 1914. Again, the excess in 1914 can scarcely be attributed to war conditions in any large measure, even taking into account the fact that most of the deaths occurred in September; in the earlier months of the war there was no scarcity of food, and therefore no great change of diet affecting infants, although the immediate increase in the price of sugar may not have been without its effect upon the feeding of children of the poorest classes. The period 1916-19 is that in which the effects of the war would be expected to be most apparent, and although the divergence of the calculated from the actual mortality in this period is very conspicuous, it is just as apparent in the two succeeding years. There is no doubt that the separation allowances made during the war, combined with the rationing of food, improved the quality and also even the quantity of food supply of the very poor—of the class, that is, in which the mortality from infantile diarrhoea is greatest. In addition there have been special administrative measures, directed to the care of expectant and nursing mothers, as well as of their infants; these were inaugurated before the war, and were further developed in spite of war conditions. Over and above these direct influences upon child welfare, there is the effect of the introduction of national insurance in bringing the practitioner into closer relations with the homes of the poor.

It is suggested that a possible explanation of the decrease in summer diarrhoea mortality in recent years is the replacement of horse traction by machine traction, and the resulting decrease in the amount of horse manure.

Enteric Fever.

During 1921, 329 cases of enteric fever were notified in London, as compared with 387 in 1920; the deaths numbered 60, as against 48 in 1920. Of the total cases notified 193 were admitted to hospitals of the Metropolitan Asylums Board, and of these it was found that 82, or 42.5 per cent., were not typhoid fever. Of the 60 deaths occurring in London 14 were inmates of county asylums outside the county boundary, and as the cases occurring in these institutions are not notifiable in London the deaths comparable with the notifiable become reduced to 46. In the 50 cases in respect of which confirmatory bacteriological results were obtained, the presence of *B. typhosus* was shown in 7 cases, 25 were described as "paratyphoid," while 6 were described more specifically as paratyphoid A and 12 as paratyphoid B. Of the 172 cases in which a possible source of infection was mentioned, the disease was described in 30 to shellfish, in 20 to fish, in 10 to watercress, and in 23 to other food; infection was attributed in 31 cases to contact with other cases. Dr. Hamer states that the practical issue with regard to typhoid fever which presses for decision at the present time is whether the control over the spread of this disease is to be maintained and further strengthened by working on the epidemiological lines (first laid down by Dr. Batstroke in his classical oyster report of 1896) or on rival bacteriological lines, in compliance with which the stress is laid on the supposed risk from healthy carriers and the need of combating this by vaccination. It has been suggested that the mischief responsible for typhoid fever in London, during at any rate the last twenty-five years, could be traced to remote estuaries and distant foreshores, and that full control of the disease is to be secured by cutting off polluted supplies of fish, and shellfish, and not by attempting to segregate healthy carriers or advocating the general practice of autityphoid vaccination.

Influenza.

During the severe epidemic of influenza which occurred practically throughout Europe towards the end of 1921 London was attacked towards the latter half of December, about a month later than the beginning of the epidemic in the Midlands; in fact, so far as can be judged from the mortality returns, influenza became epidemic in Yorkshire earlier in 1921 than in any of the principal cities on the Continent. During the course of the epidemic about 2,200 deaths in London were attributed to influenza, and taking into account deaths from complications it is estimated that not less than 5,000 deaths were caused in the London area by the epidemic. The contrast is remarkable between the age incidence of mortality in the epidemic of 1919 and in that of 1921; in the earlier epidemic the maximum mortality occurred at the ages between 25 and 35, but in the epidemic of 1921-22 the age of highest mortality was between 65 and 75, as in the epidemics of the nineties. According to the records of school attendance the number of children attacked in the last epidemic was greater than in the winter epidemic of 1919.

Encephalitis Lethargica.

During 1921 there were 243 cases of encephalitis lethargica notified, of which 87 were notified during January and 50 in February. The disease had already begun to increase in prevalence in December, 1920, and reached its climax in January, 1921. Of the 243 cases notified 45 proved not to be genuine cases, and in 9 others the diagnosis was considered to be doubtful; two further cases were recorded, but were not notified officially. Of the 191 actual cases 60 (or 31 per cent.) proved fatal.

Tuberculosis.

The death rate from pulmonary tuberculosis during the year was 1.07 per 1,000 living; the deaths numbered 4,813, as compared with 4,675 in 1920. The number of primary cases of tuberculosis notified was 12,214, as against 13,163 in 1920; of these 10,015 were pulmonary and 2,199 were other forms of tuberculosis. At ages 10 to 15 the female pulmonary cases exceeded the male by 51, or 31 per cent., but the contrast between the sexes at this age in the mortality is even greater than in the cases, the excess being 150 per cent. during the year. The National Insurance Act, 1920, provided for the discontinuance of sanatorium benefit, and by the combined operation of this Act and the Public Health (Tuberculosis) Act, 1921, the responsibility for the institutional treatment of tuberculous insured persons was transferred, as from May 1st, 1921, from the Insurance Committees to the local authorities responsible for the institutional treatment of the remainder of the population. Becoming thus responsible for the residential treatment of tuberculous persons in the metropolis the London County Council has taken steps to ensure that the best possible use is made of all existing accommodation. The number of cases requiring residential treatment has also been reduced to a minimum. It has been the policy of the Council to take advantage of all suitable accommodation already provided by hospital and sanatorium authorities, including the Metropolitan Asylums Board, and to take advantage also of additional suitable accommodation which such authorities provide by arrangement with the Council. The improved method of selecting cases for residential treatment depends upon the provision of observation beds which have been reserved at the Brompton and Victoria Park chest hospitals. The dispensary system described in last year's report has been further developed.

Veneral Diseases.

It was decided in March, 1921, to continue the scheme in force since the beginning of 1917 for the diagnosis and treatment of venereal diseases, in accordance with which the Council joined with neighbouring county councils and county boroughs to utilize the facilities afforded by certain London hospitals for treatment and to provide laboratory facilities and treatment. Arrangements were made for free treatment and diagnosis at twenty-eight hospitals and for the reception of patients for treatment at nine hostels; special provision was made for the treatment of pregnant women and very young children. During 1921 19,216 London patients attended at the hospitals for the first time, a decrease of over 4,000 from the previous year. At the end of the year there were 332 medical practitioners on the approved list (considerably more than in the previous year), and they sent 15,385 pathological specimens for examination during 1921.

THE WELFARE OF THE BLIND.

We have received three prints of recent issue which give an excellent survey of the various activities now in being for the care of the blind, particularly in relation to State responsibility.

THE REPORT OF THE ADVISORY COMMITTEE.

The Advisory Committee on the Welfare of the Blind, a committee of the Ministry of Health, has issued its third annual report, for the year 1921-22.¹ The Committee exists "to advise the Ministry on matters relating to the care and supervision of the blind, including any question that may be specially referred to them by the Minister." Since the issue of the last report the Blind Persons Act of 1920 has come into force. Section 1 of that Act provides for the grant of pensions to blind persons between the ages of 50 and 70 at the same rates and conditions as old age pensions, and it is reported that up to the end of March of this year 9,197 persons in England and Wales between those ages were in receipt of pensions. It is held that this provision has done much to alleviate the distress previously common among the blind of the unemployable class.

Section 2 of the Act imposes the duty on county and county borough councils to promote the welfare of blind persons ordinarily resident in their area, and for this purpose to provide and maintain or contribute towards the provision and maintenance of workshops, hostels, homes, and other places for the reception of blind persons, or to do any other thing approved by the Minister for promoting the welfare of the blind. It is reported that the majority of the local authorities have submitted schemes as required by this section, and that with a few exceptions it is anticipated that all schemes will be in operation during the present year. The Committee is emphatically of opinion that the best interests of the blind themselves will be served by the continuance and fostering of the voluntary side of the work, and it notes with pleasure that this is the declared policy of the Ministry. It also unanimously approves the principle that where outdoor Poor Law relief is given to the blind it should be administered under suitable arrangements through the local institution for the blind, and it recommends this principle for general adoption. Section 3 of the Act regulated the appeal by voluntary societies for subscriptions, in much the same fashion that war charities were regulated.

The Committee has been asked whether it is desirable that local authorities should themselves establish and conduct workshops for the blind as municipal undertakings. It prefers fostering the voluntary side of this work, and views the municipalization of the trading activities of the blind with a certain amount of anxiety.

"In our opinion all workshops for the blind should, as far as possible, be conducted on a proper economic basis, and it seems to us that municipalization may destroy this basis, with unfortunate effects on the morale and efficiency of the workers."

In connexion with the education of blind children, considerable alarm was felt on the issue of a circular letter by the Board of Education in January, 1922, intimating that the grants for this purpose could not exceed those of the preceding year. It is now stated that the Board has intimated to the local authorities that it will not now have to place any restriction on the full use of the accommodation already recognized. The blind workers are at an economic disadvantage, and much care has been given to the measures that should be undertaken to augment earnings without reducing the stimulus to work which earning gives. The Committee has arrived at a sliding scheme whereby the wages of workshop employees should be augmented on a sliding scale, providing for a maximum grant of 15s. a week on earnings up to 10s. a week, at standard rates of pay, decreasing by 3d. in the shilling to a minimum of 5s. a week augmentation where the wages are 50s. a week or more. The Minister has recommended this scale to the consideration of the local authorities.

Attention has been given to home workers, and an interesting departure on the part of the Birmingham Institution is reported. A travelling motor shop for the sale of goods made by the home workers visits the various markets within the area, with the result that more work has been found for these workers. Comment is made on the conditions of the grant that may have been received by the home workers, and the view is expressed that there may result some hardship unless

¹ Third Annual Report of the Advisory Committee on the Welfare of the Blind to the Ministry of Health, 1921-22. H.M. Stationery Office, 6d. net.

these be varied. Steps are being taken to improve the service rendered by the home teachers of the blind. This service is regarded as one of the utmost importance in ministering to the general social well-being of the bulk of the blind population. The scheme for the certification of these teachers has gone so far that the Committee now recommends that it would be desirable to require all home teachers appointed, on such future date as may be determined, to undergo the examination and obtain the certificate.

The number of blind persons now on the register kept by the Committee has increased from 30,785 in 1920 to 34,894 in 1921. The increase is held to be accounted for by two conditions: first, the more complete records obtained, and secondly, the finding of old blind persons owing to granting of pensions. It is not thought that the actual number of the blind has increased. The number of mentally defective amongst the blind adds to the difficulty of suitable provision. It is estimated that 40 per 1,000 are mentally defective, as compared with 8 per 1,000 amongst the ordinary seeing population. It had been hoped that the local authorities under the Mental Deficiency Act, 1913, would have been able to utilize their powers by combining to make some special provision for these persons, but the restrictions placed upon them in administering the Act by the Board of Control have rendered such assistance impossible up to the present. The Committee is making investigations into the matter, and proposes to report further. It is reported that there is need for the provision of a special home for chronically infirm blind, and that there is room for a voluntary agency to undertake this work.

The report concludes with a series of tables giving the condition of the blind, the work carried on by them, the number of unemployed, unemployable, and mentally defective. The chairman of the Committee is the Right Hon. G. H. Roberts, a Labour M.P., and the personnel number 18, all of whom are representatives of county, municipal, and Poor Law associations and of voluntary agencies for the blind.

THE LABOUR PARTY'S PAMPHLET.

In contrast with this report of work done, which is of a very hopeful character, there may be read a pamphlet issued by the Labour party, entitled *The Blind Persons Act, 1920*.³ It is a blunt and wholesale accusation against the Government and its Ministries of deliberately shirking the responsibilities placed upon them by the Act for the welfare of the blind. The reason for this attitude on the part of the Labour party is not far to seek. The pamphlet begins by setting out a lengthy resolution passed at the Cardiff Trades Union Congress, the last clause of which reads:

"Notwithstanding anything which may be done to ameliorate the bad conditions of life and labour for the blind by Acts and measures, which are mere palliatives, this Congress is resolved upon the principle of direct and complete State and municipal responsibility, and the elimination of the necessity for voluntary charity for the blind."

Thus we find there is a clear issue between the parties who report on the blind. The committee of independent persons who are at the same time actively engaged in the welfare of the blind believe in voluntary effort; the Labour party repudiate voluntary effort and desire that "the State" should take over the whole work directly.

The pamphlet has its uses: it contains a useful summary of work recently done for the blind and the ideas put forward by various agencies and associations, although the statements are a little spoiled by political propaganda sandwiched between. The point of the pamphlet is to be found in two paragraphs:

"It is already clear that in many cases there is grave dissatisfaction with the way in which the Act is being worked. It is said that local authorities are proving very lax in their duties under the Act, that the Ministry of Health is anything but eager to help, and that the benefits which have accrued to blind persons so far under the Act are very small."

"Although the Act was passed as a result of the failure and inadequacy of voluntary institutions the Ministry is attempting to place local authorities to work the Act entirely through such agencies. Capital expenditure has been prohibited, and in areas where there is no voluntary institutions the effect is practically to prevent such organizations into existence."

Some of the statements of the pamphlet are inaccurate.

The school accommodation for blind children remains hopelessly inadequate, and the voluntary agencies are quite incapable of providing a remedy."

The Blind Persons Act, 1920. Published by the National Joint Council of the Trades Union Congress and of the Labour party, Eccleston Square, London. (Undated.) 3d.

The inference is that all schools for blind children are voluntary agencies, which is not true; and that such voluntary schools as exist are incapable, which is equally untrue. It would be well if the sponsors of the paper visited some of these schools; there are a dozen in London within a bus ride of Eccleston Square. Again, it is stated that the "economy" circular of January of 1922 is still in force, but that, we are informed, is not so. There are some appendices, one of statistics taken from last year's report of the Advisory Committee, and a copy of the Birmingham Scheme in operation under the Act of 1920. Presumably this scheme is cited as a model, yet we find that it provides for the full use of the local voluntary institution, and other voluntary institutions set up by the National Institute for the Blind, in the assistance of blind persons, both children and adults. Truly the citation of this scheme is better than the damning charges of the pamphlet.

THE NATIONAL INSTITUTE FOR THE BLIND.

By way of affording some criteria of the value of voluntary work we may give a short summary of the work of the National Institute for the Blind, which has just issued its report for the year ending March, 1922.³ This Institute was described in the JOURNAL in 1914, the date of the opening of the new premises in Great Portland Street, London, as "the University of the Blind," and it well merits the name, for there is scarcely a feature of the life of the blind which it does not touch. It is now not only the largest institution of its kind in the United Kingdom, but throughout the world. During the past year it collected and administered funds to the amount of £324,000—no small revenue. The account of the manner in which this sum was dealt with is given in a crisp, terse document of 39 pages, including the several statements of account. The Institute is rapidly becoming the foster parent of many other societies for the blind; it collects money and distributes it to the smaller societies, and in so doing it helps to co-ordinate activities and prevent overlapping of effort. In this manner some hundred thousand pounds were distributed last year.

The Institute has founded and maintains Sunshine House for blind babies, particularly for those whose homes are unsatisfactory. The present home is in Herts, and it hopes to establish one for the north of England shortly. It maintains two first-class colleges for the blind, that at Worcester for boys and that at Chorley Wood for girls. The value of these colleges cannot be overestimated, for they provide a public school education of the best type—a most necessary provision for the blind, for if the blind are to be teachers of the blind the prospective teachers must receive an education of such breadth as will lift them out of the narrow groove in which the blind are apt to move. It is the chief printing and publishing agency of books for the blind, both in braille and Moon's types. Books are a boon to the sighted; they are a positive necessity to the blind, for through them alone can they enter into the chief avenues of thought and inspiration, which are the treasures of our civilization. The books are sold on such terms that there is a heavy annual loss, which has to be made up by benefactions to the extent of £7,000 per annum. The works printed include all manner of educational and scientific works, and those necessary for university students, of which there are not a few. There is also a large output of music sheets in braille.

The Institute issues no less than ten newspapers and periodicals. It has a massage school from which 152 students have qualified, a special library for these students of 493 volumes in charge of a blind medical man, and through the after-care department it assists its workers to obtain suitable posts. It has a staff of thirty-nine home teachers for the blind whose work is chiefly the teaching of those recently blinded. In addition to all this it maintains four guest houses, homes, or hostels for the blind. That is no small record for a voluntary institution. And those who have had experience of the manner in which this Institute takes up the case of a blind person referred to it for help in training or in obtaining suitable work can testify to the alertness of its officers and to the lack of red tape which marks their procedure.

On the testimony of the report of this voluntary institution we think that the Labour party is wrong in belittling voluntary effort, and that the Advisory Committee is right in recommending the Ministry of Health to use such voluntary effort in preference to municipal machinery.

³ *The Annual Report of the National Institute for the Blind, 1921-22* Great Portland Street, London, W.1.

England and Wales.

CARDIFF OUT-PATIENT CLINIC IN PSYCHIATRY.

IN his last annual report on the work of the City of Cardiff Mental Hospital* the medical superintendent, Dr. Edwin Goodall, makes interesting reference to the out-patient clinic in psychiatry, which was started by him in May, 1920, with the joint approval of his committee and the authorities of the King Edward VII Hospital, Cardiff. This clinic is held every Tuesday afternoon in the out-patient department of the general hospital. Its purpose is to give advice and treatment (a) in early and recent cases of the psychoses and psychoneuroses; and (b) to patients who have been under treatment in the Mental Hospital, both during their period of discharge on probation, and subsequently if they feel in need. Dr. Goodall states very cogently his reasons for securing that the psychiatric clinic should be part of the out-patient department of the general hospital, and not merely an out-patient department of the mental hospital. He regards the setting up of this clinic as a step of the first importance in the treatment of mental and allied disorders, and two years' experience strengthens him in his insistence on the urgent need for an indoor psychiatric clinic to work in conjunction with it. The out-patient department, he declares, will not be fully successful until suitable indoor accommodation is available. Meanwhile, in co-operation with the medical staff of the King Edward VII Hospital, certain cases of a suitable kind have been received into that institution under the physicians, thereby securing for the patients that investigation from the standpoint of general medicine which is what they need. Dr. Goodall acknowledges his gratitude to the physicians for letting him collaborate with them in this matter. To illustrate the kind of cases dealt with at the clinic he classifies the first hundred patients into groups, and from this he infers that "in Cardiff medical ideals in regard to the treatment of early mental and allied disorders have been attained as nearly as they can be, failing the indoor clinic in psychiatry, which is bound to come sooner or later."

MANCHESTER ROYAL INFIRMARY.

A bazaar is to be held on the first three days of November for the purpose of raising the first £10,000 of a £100,000 fund which is required to build a new nurses' home for the Manchester Royal Infirmary. The great expansion of the work of the Infirmary since the new buildings were opened some thirteen years ago has made a new nurses' home necessary. When the new Infirmary was built accommodation was provided for 189 nurses, but with the increased staff many nurses have now to be lodged outside, an arrangement which has obvious inconveniences. Nurses on night duty have now a 73-hour week and on day duty a 63-hour week. It is agreed that these hours of duty are much too long, and the Board of Management is anxious to reduce them. A uniform week of 56 hours for both day and night duty is aimed at, but for this reduction at least 65 more nurses are required. It is to accommodate those 65 nurses and to bring under one roof the other nurses who are at present compelled to live outside the Infirmary that the new home must be built. Gifts of money and goods for the bazaar may be sent to Miss M. E. Sparshott, matron, Royal Infirmary, Manchester.

Scotland.

PROFESSORIAL APPOINTMENTS FOR GLASGOW GRADUATES.

As we briefly announced last week, Dr. G. Haswell Wilson has been appointed professor of pathology in the University of Birmingham in succession to Professor J. Shaw Dunn, who has been elected to the corresponding post in the University of Manchester. Both Dr. Wilson and Professor Shaw Dunn are graduates of the University of Glasgow, the former having graduated M.B., Ch.B. (with commendation) in 1906, and the latter M.B., Ch.B. (honours) in 1905 and M.D. (honours) in 1912. Dr. Wilson, after holding a Carnegie Research Scholarship and Fellowship, was appointed assistant to the professor of pathology and assistant pathologist to the Western Infirmary, Glasgow, in 1911, and three years later became lecturer on

* City of Cardiff Mental Hospital. Fourteenth Annual Report for the year 1921. Cardiff: S. Glossop and Sons, Ltd.

pathological histology in the University; in 1918 he was appointed lecturer in bacteriology, and in the following year pathologist to the Royal Hospital for Sick Children.

MEDICAL LUNCH CLUB, GLASGOW.

This club resumed its activity for the season on September 7th, when Dr. John Henderson presided over a good attendance of members. After lunch various items of business were discussed. The place, day, and hour of meeting were adhered to as formerly, being considered most suitable and it was decided to resume the weekly meetings for the season on October 5th, when office-bearers would be appointed for the year. The report of last year's working was favourably received, and it was unanimously agreed that the club fulfilled a useful function amongst the profession in Glasgow but that its usefulness could be much greater were its membership increased. To this end it was emphasized that although the club was instituted under the auspices of the Glasgow Eastern Branch of the British Medical Association its membership was open to all practitioners in Glasgow and neighbourhood.

ANDERSON COLLEGE OF MEDICINE.

At the last quarterly meeting of the governors of the Anderson College of Medicine, Glasgow, it was announced that Professor J. Arthur Thomson of Aberdeen would give the introductory address at the opening of the winter session. The resignations were received with great regret of Dr. J. Macintyre from the lectureship on diseases of the throat and nose and of Dr. W. D. Macfarlane from the professorship of midwifery and gynaecology. Dr. Macintyre has held his appointment for thirty-one years, and is also Dean of the Medical Faculty of the college; Dr. Macfarlane has been professor of midwifery for the past eleven years. The report on the work of the summer session showed that the number of students attending was 357.

India.

WOMEN'S MEDICAL SERVICE.

THE annual report* for 1921 of the National Association for Supplying Medical Aid by Women in India shows that the work of the Association and its affiliated institutions is continuing to make excellent progress. On January 1st, 1922 there were thirty-three medical officers on the cadre of the Women's Medical Service for India. It is stated that the work done in most of the hospitals under the control of the Service has been excellent, and in nearly all of the the numbers treated have increased. The financial position is difficult on the whole; but in some cases improvement has taken place owing to the increased popularity of the hospital leading to a larger number of subscriptions and the realization of larger sums from hospital stoppages. According to the appendix in the present report there are now no fewer than 135 women's hospitals in India, large and small (including mission hospitals), staffed entirely by women. The Laing Hardinge Medical College continues to prosper, and there are eighty-five students in residence. The course of study at the College lasts for seven years—two in science and five in medicine; as the College was opened less than six years ago no medical graduates have yet passed out, but in May, 1923, nine students will appear at Lahore for a final M.B., B.S. examination, and thereafter the College should turn out annually an increasing number of highly qualified medical women. The ordinary income of the Countess of Dufferin's Fund, upon which the provision for training of medical women and the upkeep of women's hospitals in India largely depend, amounted to Rs. 47,177, at the ordinary expenditure of the council of the Fund during the year was Rs. 36,124. A subsidy of Rs. 4,24,455 was received from the Government of India to meet the cost of the Medical Women's Service for India. The year closed with a balance in hand of Rs. 2,65,748. The Countess of Reading, who has taken a great interest in the organization of the medical relief of women since her arrival in India, has issued a public appeal for a "Women of India Fund," which it is hoped will remain permanently open and will help from time to time to assist departments most needing help.

* Annual Report of the National Association for Supplying Medical Aid by Women in India for the Year 1921. Calcutta: Superintendent Government Printing, India. 1922. 1 rupee 8 annas.

In the first instance it will be used to complete the buildings of the Lady Harding Hospital, Delhi, and then to open a women's hospital in Simla; later it is hoped to further the organization of an Indian nurses' association.

NEW MEDICAL COLLEGES FOR BENGAL.

Sir Surendra Nath Banerjee, Minister of Public Health, presided at Calcutta over the inaugural meeting of the National Medical College and King's Hospital, a private medical institution founded in Calcutta, which will be affiliated to the State medical faculty. The Minister said that there was a paucity of qualified medical practitioners in India, and the Provincial Government would rejoice if more medical schools were established. Two more medical schools were, he said, in fact likely to be started shortly—one in connexion with the Sambunath Pandit Hospital, and the other at Howrah. The Burdwan Schools were already started, and others were in course of preparation at Mymensingh, Chittagong, and Berhampore.

CONVICTION UNDER BOMBAY MEDICAL ACT.

At Bombay, in June last, a man named J. F. C. Wood was charged, under the Bombay Medical Act, with assuming certain medical degrees to which he was not entitled. A full report appears in the *Pioneer Mail* for July 7th, 1922. The accused applied to the registrar of the Bombay Medical Council for permission to register as a medical practitioner; the reply to an inquiry addressed to the General Medical Council was unfavourable. The accused stated that his diplomas were deposited with his mother before leaving on field service for Mesopotamia, and he had since lost trace of his mother's whereabouts. He did not know why his name did not appear on the *Register*. He undertook not to practise medicine or surgery until he had satisfied the Bombay Medical Council. The magistrate found the accused guilty, and fined him 201 rupees.

PRESENTATION TO DR. N. H. CHOKEY.

Dr. N. H. Choksy, late of the Bombay municipal health department, was recently presented with an address in a silver casket by the Bombay Medical Union and other medical friends. The address referred to Dr. Choksy's eminent public services, extending over thirty-four years, and especially to his devotion to duty during many serious epidemics. Dr. Choksy has also been honoured by the King by being made a Companion of the Order of the Indian Empire.

Correspondence.

BONE GRAFTING IN TUBERCULOUS SPINAL CARIES.

SIR,—I would not like that through Mr. Roth's letter (August 12th, p. 284) on the subject of bone grafting in spinal caries a misunderstanding should arise concerning my methods for the reduction of deformity.

We do not try to obtain the straightening of the deformity caused by the cicatrized vertebral bodies, but we reach its apparent reduction by its soft and progressive driving back by means of compensatory lordoses above and below the formerly diseased region. What still subsists of the deformity is concealed by the muscles which are remarkably developed by heliotherapy. Because these compensatory lordoses are necessary it is very much more easy to get a reduction of deformity in the dorsal region than in the cervical and lower lumbar regions. This explains why I could once write to Mr. Roth:

"The gibbosity, when situated in the dorsal and also dorso-lumbar region, has, as a rule, been corrected, and always given us the best results."

With regard to the question of immobilization, it is our practice to keep the patient strapped down flat upon his back during the active stages of the disease, and not to allow the change to the ventral position (which is so potent in the correction of deformity) until clinical and radiographic examination show the disease to have entered on a quiescent stage.

In his statement, that relapse is less common after operative than after conservative measures, I think Sir Henry Gray must have the plaster jacket in mind, more than other methods of conservative surgery. The muscles, whose function it is to support the spinal column in an extended

position, are so atrophic after a long course of plaster-jacket treatment that far too much weight is thrown on the anterior part of the vertebral bodies, with the result that the disease is likely to be reawakened. The splendid "muscular corset" developed by patients treated by heliotherapy makes them often look like athletes, achieves quite as satisfactory a result as an Albee graft, and does so in what is, to my mind, a much more natural way.

My own experience is that treatment directed towards the rehabilitation of the general health is a much more effective way of guarding against relapse than any form of local treatment. I am becoming more and more convinced that tuberculosis is to be looked on merely as a local manifestation of a general disease, and it would really be a pity if by Albee's operation this fact were to become forgotten.—I am, etc.,

Leysin, Sept. 16th.

A. ROLLIER.

OPHTHALMIC EXAMINATIONS IN GENERAL MEDICINE.

SIR,—Dr. Hawthorne's paper in the *JOURNAL* of September 16th (p. 495) on "The significance of retinal haemorrhages" calls attention to the necessity and usefulness of ophthalmic examination in the practice of medicine, and yet, sad to say, how few men use the ophthalmoscope in their daily practice.

With the electric ophthalmoscope there is little difficulty in quickly obtaining the required manipulation of the instrument. It is one of the drawbacks of the extreme prevalence of specialties in every branch of our profession that many men are gradually but surely giving up the use of special modes of examinations, which are not difficult to learn, and are allowing them to be placed in the hands of a few special men. It is well known that a large number of so-called eye cases occurring in practice are primarily medical cases, and really should be diagnosed and treated by physicians.—I am, etc.,

Folkestone, Sept. 18th.

W. J. TYSON, M.D., F.R.C.P.

AN UNSUSPECTED PREGNANCY.

SIR,—After reading Dr. Fletcher's communication on unsuspected pregnancy in the *JOURNAL* of September 16th (p. 516), and in view of its medico-legal significance, I send you the following record of an experience I had in a similar case.

Early one morning a few years ago I was called to a lady visitor who had been taken ill suddenly at an hotel. I found she had just been delivered of a full-time healthy child, no one, also being present in the room, and no one knowing she was in labour. The baby was born into the *pot de chambre* and fortunately survived the ordeal. The umbilical cord had been torn across, no ligature had been applied, and there had been no unusual amount of haemorrhage, either maternal or umbilical. I expressed the placenta, gave the usual attendance, and the subsequent history was uneventful. She was a married woman and this was her first pregnancy. She had no idea that she was pregnant, and said that her menses had been perfectly regular, the last occasion being one month previous to her confinement. Her mother, with whom she had lived several months during her pregnancy, corroborated this statement. She was employed by a firm of wholesale costume manufacturers as a mannequin, and the afternoon before this event took place had been displaying evening dresses and costumes on her figure with their representative. This man, who was married and the father of a family, had detected nothing unusual about his assistant. In the early part of the night she had complained to him of abdominal pains, and he had given her some whisky. He was very much surprised to hear next morning what had happened. A few weeks later the husband wrote to me and I furnished him with a full report of the case. Since then I have heard nothing more of the patient.—I am, etc.,

Manchester, Sept. 17th.

ALFRED WILLIAMS, M.D.

PSYCHO-ANALYSIS.

SIR,—We are fortunate with men like Dr. McBride having leisure and ability to draw our attention to the antitheses of writers on dreams and other nervous phenomena, and probably his modesty makes him apply the word "desultory" to his study of such subjects.

Many years ago, when making extracts from Continental writers on dreams and other nervous states, one of my assistants suggested that some of the patients seemed acquainted with "leg-pulling," and during and since the war patients have been known to elaborate hypothetical dreams

in anticipation of an impending interview with psychoanalysts. There seems no reason why this old soldier should not be played on psychic as well as other ailments.

In your article on shell shock at page 392 of the *JOURNAL*, you quote an eminent authority as stating: "The war created nothing in the way of psychoses." During the war, however, many doctors joined the forces, and were brought up against soldiers with nervous troubles, and having had no special training or experience in such conditions deemed what they observed as new, not only to themselves but to others.

Dr. Adamson in his letter (p. 402) defines the chief duty of a psychoanalyst, and it seems dangerously near to using leading questions, which often enables one to obtain the replies wished for. Psycho-analysis resembles in no small degree the detailed and painstaking history of any given case, and we would be equally justified in using such terms as cardio-analysis or pelvic analysis, according to the position of the symptoms or ailment.

In the *Journal of Mental Science* for July there are two such cases well reported, and Dr. Good is worthy of all praise in restoring two cases of supposed neurasthenia to their proper place of traumatic nervous diseases, but psycho-analysis does not seem the prime factor in the diagnosis.

The words "conscious" and "unconscious" have supplied food for metaphysical discussion for centuries; hence the variety of terms concerning them. The conscious may be readily recognized, but not so the unconscious. A muscle not active is said to be at rest and ready to act again if required; it is not said to be palsied. So should we hesitate to apply "unconscious" to any part of the brain for the moment inactive. Rather should we say it was at rest, and in fact use the word "unconscious" as seldom as possible, preferring to qualify the word "conscious."

Sir W. Hamilton, following Horace after a lapse of nearly two thousand years, revived two words easily understood, in common use in other sciences, and applied them to conscious states—namely, "latent" and "potential"—the former meaning a conscious which was and may be again, the latter an actual or potential state and which now is.

The greater part of our knowledge lies in the domain of latent consciousness, ready for use when required.

May I remind Dr. Laddell that at Edinburgh University during the summer sessions over fifty years ago a very complete course of lectures on medical psychology was delivered, combined with clinical instruction twice a week at Moringside Asylum?—I am, etc.,

Harrogate, Sept. 5.11.

T. JOHNSTONE, M.D.

STERILIZATION OF MENTAL DEFECTIVES.

Sir,—It is impossible to answer Surgeon Commander Bastian (September 9th, p. 490) fully in a letter. He raises issues on which hang questions not only of science, but of practical policy, many of them connected with mind, of greater importance than even the prevention of idiocy.

What is the nature of man? What in him is innate, what acquired, and what inherited? What can be effected by mere training, and what only by selective breeding? What lines should training, and, if absolutely necessary, selective breeding, follow? All these problems, linked with every detail of human life, are discussed on platforms and in pulpits and print every day, but with futility; for, since crucial tests are rarely applied, and never frankly accepted, there is no agreement as to basic principles. It is about these basic principles that Surgeon Commander Bastian inquires. I am very sure that doctors are the only considerable body of men who are fitted by knowledge and training to apply the right tests and trace the inevitable consequences, and equally sure that before long they will do so; but hitherto, though eager as individuals they have as a body fought shy of problems that seem remote and complex. Actually the necessary facts are in the hands of all doctors, and for people who think in terms not of mere words, but of reality, the problems themselves are simple. In what follows I shall give the appearance of controversy, for I deal with debated matters and must indict a whole "science." But of controversy, based on preconceptions and mere words, we have had enough outside the ranks of medicine. A little cool discussion, founded by doctors on verifiable evidence, conducted in precise language and with an open-minded readiness to accept crucial tests, should soon put a new aspect on affairs. May I, therefore, beg each reader to judge from facts within his own knowledge?

As stated in my letter (August 26th, p. 401), the individual springs from a germ cell in which are none of the features

(characters) that he develops subsequently, but only predispositions to develop them in response to fitting nurture. It follows that he inherits only predispositions, and that every character he develops is a product of nature and nurture. Because men and trees have different natures they require different natures and develop differently. Speaking generally, the individual develops characters only when they are needed. Some characters (for example, head and heart) are always needed, and therefore Nature has arranged that the necessary nurture shall always be experienced. Other characters (for example, scars which repair injury and blacksmith's muscles which follow heavy labour) are only exceptionally needed, but, provided the individual's nature permits, they arise just as surely as the head and heart when the proper nurture is experienced.

We know that the differences between two separate individuals are natural or nurtural. Thus a man may be darker than his parent by nature or through sunbath. Here the thinking is clear and the language precise. Technically, natural (innate, germinal) differences are termed "variations," while nurtural (acquired, somatic) differences are called "modifications." We know what we mean when we say that variations are inheritable—that is, that differences in predispositions tend to be transmitted to offspring, so that given similar nurture they develop similar differences. But can any man explain precisely what he means when he says that modifications are (or are not) inheritable? If he tries he will find that he is playing with words, and confusing inheritance with reproduction, or even with non-inheritance. But in this connexion modifications belong to the same category as characters about which Surgeon Commander Bastian inquires.

First, let us note that variations and modifications are not characters, though they are revealed in characters. We can always contemplate a character in a single individual, but we cannot perceive a variation or a modification unless we compare separate individuals. Thus, if a normal man's son has a sixth digit, then that digit is a character which indicates that the son has varied from his parent. If the grandson reproduces the digit it remains a character, but no longer indicates a variation from the parent. Clearly, then, variations and modifications are not characters, but relations of difference between individuals—parent and child, grandparent and grandchild, negro and white, and so on. Nevertheless they are constantly confused with characters, and just here has been the starting point of an enormous amount of loose thinking and writing.

As we see, differences between individuals (variations and modifications) are innate or acquired, natural or nurtural, germinal or somatic in origin. But in what sense is any character more innate or acquired than any other?

If we compare two men we can say with clear meaning and in precise language that they differ innately as regards heads, and by acquirement as regards scars. But if we compare a man's characters and say, for instance, that the head is innate and the scar acquired, what in the world can we mean? Head and scar are both products of ancient evolution, both depend on germinal predispositions and fitting nurture (and on nothing more and nothing less), and both are situated in the soma.

Obviously, therefore, characters, unlike differences between individuals, are both natural and nurtural; innate and acquired, germinal and somatic. I hope I have managed to make myself clear, for here—in the fact that differences between individuals are innate or acquired, whereas the characters in which those differences occur are themselves innate and acquired—we have, I think, the key to the whole problem. Missing the key, we have before us nothing but a continuance of that immense mass of loose thinking and unending controversy which has disgraced this subject for more than a century; holding it, the door opens and the road before us is plain. Missing it, we shall deal only with words; holding it, we shall be in contact with the realities of nature. There are sure to be readers who think I am exaggerating. Well, let them try to conceive of a character as innate or acquired.

Contemplate the consequences of loose language and thought.

Consider such a sentence as the following, the like of which may be found in almost every page of biological literature. "John's head is innate, but his scar is acquired, and therefore his child inherits the former, but not the latter." In the case of the head, since only predispositions are transmitted, we can mean only that the child, inheriting John's predisposition, reproduces, in response to similar nurture, a similar character. The child is, then, like his parent both by nature and nurture. If we give our words the same meanings, we should say that a child inherits a scar when he reproduces it in the same way as the parent produced it. Again, he is like the parent both by nature and by nurture. But biologists, who are nearly all zoologists and botanists, would not regard this as inheritance. They would regard the scar as inherited only if the child reproduced it in a way in which the parent did not, and could not, have produced it.

He would then, notwithstanding a superficial resemblance, be profoundly unlike the parent both by nature and by nurture. But unlikeness is not inheritance. It is variation—that is, non-inheritance. So that here, in a single sentence, "innate" and "acquired" are used to indicate distinctions where there are no differences, and "inherit" is given two directly contrary meanings. Is not this a mere playing with words? Conceive the confusion of thought and language! As Francis Bacon said: "Men believe that their reason rules over words, but it is also the case that words react, and in their turn use their influence on the intellect." Here the transference of three words from differences between individuals to the characters in which the differences are revealed has resulted in a century of stasis in what should be the queen of sciences. Not even the old schoolmen produced anything so merely verbal.

Characters result from the action of nurture on predisposition. Nature has evolved these actions and reactions to fit species to their environments, and therefore normal characters, normally developed (for example, a scar when it repairs injury), are always useful. For millions of years living beings develop characters normally, but at long last a biologist observes a character which he calls "acquired," and wonders whether it is "inheritable." Thereafter he, his fellows, and their successors debate the matter for a century! Such is the power of words. What they mean, if they mean anything, is that when the "acquired" character is observed the whole scheme of nature totters, astoundingly, to be upset, and that this useful feature tends henceforward to appear a useless thing in response to a new form of nurture. Of what use, for example, would scars be to the unwounded descendants of a wounded man, or big muscles and horny hands to the sedentary descendants of a blacksmith?

Which are the characters which biologists distinguish as innate, and which those they call acquired? Such is the power of tradition—that is, words—that they have followed without question the man in the street, who, in thoughtlessness, has always called everything which develops in response to glaringly obvious nurture "acquired," and everything else "natural." The distinction is good enough for his purposes, but it is not for science. Thus, though human muscles develop from birth forwards solely in response to use, of only exceptional muscular developments such as the blacksmith's are described as acquired by biologists.

It is sometimes maintained that "innate" and "acquired" are eulachinal terms; but, as may be seen plainly in literature, biologists have genuinely supposed that some characters are products of nature without nurture, and others of nurture without nature. Hence their terms "germinal" and "somatic." The matter has been discussed at length (*Nature*, November, 1920; May, 1922), and, though many biologists declare that they know exactly what their terms mean, all attempts to explain or define have failed. Some have said that "innate" implies normal and "acquired" exceptional. But why not use precise language? Besides, many exceptional characters (for example, birthmarks) are regarded as innate, and many normal traits (for example, knowledge of the English language in England) are considered acquired. Others, again, say that an acquired character is one which develops in response to the action of use, and that all others are innate. But many characters (for example, scars) which are termed "acquired" do not develop in response to use, and most characters which do so develop (for example, ordinary muscles) are termed "innate."

With the conspicuous exception of Darwin, who, in all that remains valid of his work, reasoned from the basis that variations are innate and transmissible, most biologists—for instance, Lamarck and Weismann—have founded their speculations on the idea that characters are innate or acquired, transmissible or non-transmissible. This is the basis of modern biology. Taking that much for granted, and assuming also that nature and nurture are warring forces, they have tried to ascertain, for example, what is innate and what acquired in the individual, and whether nature or nurture is the stronger—which is like trying to discover whether the engine or the steam is the more potent in moving the train. The significant thing in all this for medical men is that our own science, physiology, is in direct opposition. Physiologists assume that nature and nurture are collaborating forces; suppose, therefore, that all characters are equally innate, acquired, and transmissible; and, taking predisposition for granted in every case, seek merely to ascertain what natures cause what characters to develop. We know clearly what physiologists mean; but can any biologist explain in precise terms what he means? Physiologists have a large body of interpretation, the truth of which is universally admitted, but there is hardly an item on which biologists are agreed. Physiologists proceed on the assumption that normal characters have, or had, functions, and already in the case of man, the best known living being, have ascertained the utility of almost every feature; but biologists are still disputing as to whether living beings are adaptional forms. In brief, physiologists have followed Bacon's advice and founded their science on reality, whereas biologists, like the schoolmen whom Bacon is

supposed to have destroyed, have based their disputations on misused words. Hence the mending controversies.

The amusing thing is that biologists have always assumed an air of patronage towards medical men, who are supposed to be too ignorant or untrained to grasp the subtleties and complexities of heredity. Even decisive medical facts have been consistently ignored. I suppose some doctors have been hypnotized; but it is all crazily absurd. There is not a big problem about which biologists have disputed which could not be settled immediately if undisputed medical evidence were used cruelly and with ordinary common sense. The simple physiological truth, "Variations are the sole cause of non-inheritance; apart from variations, like begets like when parent and offspring develop under like conditions of nurture," covers almost the whole field. There remains nothing besides but the causation of "spontaneous" variations and the function of sex (with which is bound up the problem of alternate inheritance and reproduction). Both these problems are physiological. Of course, however, when the basic truths are established, there remains an enormous field for application—as, for instance, in the prevention of idleness and the training of normal children.

I venture now to raise a question which seems to me important. Medical science has grown so enormously that we are all ignorant of much which we should know. Even six years of strenuous labour leave the student inadequately trained. Knowledge is worthless unless it be useful practically or intellectually. Is it right to compel learners to spend valuable time over the traditional zoological and botanical studies? The information acquired is of little practical utility to the physician or surgeon, and is, as a rule, forgotten as soon as the prescribed examinations are passed. For the same reason it is useless intellectually. Moreover, consider the dismal mess that lifelong students of natural history have made of their own thinking. Is it not high time that medicine cut her leading-strings and established her own biology and study of heredity on what has never yet been done—a physiological basis?—I am, etc.,

Southsea, Sept. 17th.

G. ARCHBOLD REID.

Obituary.

JAMES DONELAN, M.B., M.Ch.(R.U.I.),
Surgeon, Throat and Nose Department, Italian Hospital, London.

MR. JAMES DONELAN, well known among London laryngologists, died on August 25th at the age of 65. He received his medical education at Trinity College, Dublin, and the *École de Médecine*, Paris, and graduated M.B. and M.Ch. (with honours) at the Royal University of Ireland in 1886. After holding several resident appointments in Dublin he became a clinical assistant at the Throat Hospital, Golden Square, London, where he was associated with Sir Morell Mackenzie. He acted as private assistant to Mackenzie for nearly five years, and helped him with the (unpublished) revised edition of his work on diseases of the nose and throat; he was in charge of Mackenzie's practice while the latter was in Germany in attendance on the Emperor Frederick. Mr. Donelan was appointed surgeon to the throat and nose department of the Italian Hospital, Queen Square, in 1895, and held that appointment until his death. He was made a Chevalier of the Crown of Italy in 1909, and promoted Officer in 1918. During the war he was responsible for the organization of the "short service" system by which over 300 British and colonial surgeons gave voluntary service to the French wounded from 1914 to 1916, and he acted as surgeon in charge of the Ambulance Hospital, Crépy-en-Valois, during the first battle of the Aisne. He had been honorary secretary and a member of the council of the Laryngological Society of London, and in 1918-19 he made a most popular president of the Section of Laryngology of the Royal Society of Medicine, of which he was a Fellow; his presidential address on "Morell Mackenzie, the father of British laryngology," was published in the *Journal of Laryngology and Otology* in June, 1919.

James Donelan will perhaps chiefly be remembered as a genial link between the early days of laryngology in England and its status as a surgical specialty to-day. His private charities were many, and the poor—notably those of his own church—were always a particular care to him. In his younger days he had been an oarsman of some note, having won several cups, and latterly he was a great lover of music, books, old silver, and furniture. His death may have well been hastened by his strenuous work in Paris during the

recent International Congress of Oto-Laryngology; he was a member of the committee of organization, and spoke each day in English, French, and Italian, interpreting the speeches of other members of the Congress. He is survived by his widow and daughter, and a son who qualified lately as a medical man from St. Bartholomew's Hospital.

THE death took place, on September 4th, of Dr. JOSEPH CARROLL of Whalley, Wigan, in his 63rd year. He was educated at Glasgow University and Anderson College, and graduated M.B., C.M.Glasg. in 1882; he took the D.P.H. at Cambridge in 1891. He was for a time lecturer in hygiene and public health at Anderson College, and later went into practice at Ilkeston, Derbyshire, where he held the appointments of surgeon to the Ilkeston Cottage Hospital and medical officer of health. During the war he held a commission as Captain in the R.A.M.C.(T.), and served with 2/3 Welsh Field Ambulance in various theatres of operation. He was medical officer for the Wigan Union, and held the post of medical officer for the Wigan district under the Ministry of Pensions.

The Services.

DEATHS IN THE SERVICES.

Lieut.-Colonel Walter Croker Thomas Poole, R.A.M.C.(ret.), died at Caxton, Cambridge, on September 9th, after a long illness, aged 69. He was born on November 12th, 1853, and was educated at Trinity College, Dublin, where he graduated as A.B. and M.B. in 1878, also taking the L.R.C.S.I. in the same year, and subsequently the F.R.C.S.I. in 1890. Entering the army as surgeon on February 5th, 1881, he became lieutenant-colonel after twenty years' service, and retired on February 14th, 1903. He served in the South African war in 1900-02, and took part in the relief of Ladysmith, including the actions at Spion Kop, Vaal Krantz, and Pieter's Hill, and the operations in the Tugela Heights; in the operations in the Transvaal from March to June, 1900, including the action at Laing's Nek; and in the Transvaal from November, 1900, to May, 1902; receiving the Queen's medal with five clasps, and the King's medal with two clasps.

Medical News.

THE winter session 1922-23 at Charing Cross Hospital Medical School will be opened by the annual prize distribution, which will take place in the Out-patients' Hall of the hospital on Tuesday, October 3rd, at 3.30 p.m. Viscount Burnham will distribute the prizes. The annual dinner of past and present students will be held at the Imperial Restaurant (Oddenho's), Regent Street (entrance in Glasshouse Street), on the evening of the same day, at 7 for 7.30 p.m., with Lord Burnham in the chair. Tickets, 12s. 6d. each, can be obtained from the honorary secretary to the dinner, Mr. Frank Noakes, Charing Cross Hospital, London, W.C.2.

AN autumn special course, arranged by the North-East London Post-graduate College, will be held from October 16th to October 28th inclusive, at the Prince of Wales's General Hospital, Tottenham, N.15. As on former occasions it will include, in the mornings from 10.30 a.m. to 12.45 p.m., practical demonstrations of clinical methods applicable in medical practice, the exhibition of illustrative cases, etc., and in the afternoons, from 2 to 5.30 p.m., demonstrations of groups of selected cases, clinics in the various general and special departments of the hospital, and clinical lectures. On Saturdays demonstrations will be given in adjacent special hospitals. Luncheon will be obtainable in the neighbourhood of the hospital, and tea will be provided each afternoon. A syllabus of the course with any further information desired may be obtained from the Dean.

THE League of Nations Committee for the study of international questions concerning intellectual co-operation held a session at Geneva last month under the chairmanship of Professor Henri Bergson. It was decided that arrangements should be made to hold an international congress of the universities of all countries. The subcommittee charged with the arrangement of this congress was instructed to prepare a report on the following topics: The exchange of professors and of students; the equivalent values of university courses and degrees; the institution of international scholarships, of international vacation courses, and of a central office for information on university matters.

It is announced that Dr. Wilbur C. Smith will combine the appointments of "athletic director" and professor of anatomy at Tulane University, U.S.A.

FRIDAY, October 6th, has been set apart for an organized effort in London under the patronage of the Prince of Wales, on behalf of the Joint Council of the Order of St. John and the British Red Cross Society and the Combined Hospitals of London.

THE annual general meeting of the Medical Sickness Annuity and Life Assurance Society will be held at the offices of the society, 300, High Holborn, W.C., on Monday, October 2nd, at 4 p.m.

THE winter session of the Harveian Society will open with a clinical meeting, to be held at Paddington Green Children's Hospital, on Thursday, October 5th, at 4.30 p.m., when many interesting cases will be shown.

AT the opening of the new session at the Westminster Hospital School of Medicine on Monday, October 2nd, at 3 p.m., Mr. G. T. Mullaly, assistant surgeon to the hospital, will give the introductory address, "The art of medicine."

MEDICAL practitioners are sometimes asked where instruction in infant care may be obtained by lay workers. Elementary courses in this subject are given at Carnegie House, 117, Piccadilly, W.1, under the auspices of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy, and the National Society of Day Nurseries. The next courses of lectures for crèche nurses and probationers, on the one hand, and for infant welfare workers, teachers, mothers, etc., on the other, will begin early in October. Applications should be addressed to the Honorary Secretary, Miss Halford, at the above address.

THE University of London Press announces for early publication a study of the human mind, from the metaphysical and neurological aspects, entitled *Elements in Thought and Emotion*, by Mr. George G. Campion, who has had assistance from Mr. Santayana and Professor G. Elliot Smith.

A COURSE of twelve lectures on the management and feeding of infants and young children will be given to qualified practitioners by Dr. Eric Pritchard, at the St. Marylebone General Dispensary, on Thursdays and Mondays from October 5th to November 13th, at 6 p.m. Arrangements have been made for those taking part in the course to attend the infant consultations at the Infants' Hospital, Westminster, and to visit the Nursery Training School at Golders Green. The fee is two guineas; information and tickets may be obtained from the Secretary, 77, Welbeck Street, W.1.

THE Rhode Motor Company of Tyselcy, Birmingham, is advertising a new Rhode "all weather" coupé at £325. The chassis is the standard 9.5-h.p., with the Rhode four-cylinder water-cooled overhead valve engine.

DR. JORICHI TAKAMINE, well known for his work on diastatic ferments and the active principles of the suprarenal glands, died recently in New York; he was born in Tokyo in 1854.

THE medical officer of health of Toronto recently stated in a health bulletin that there were more deaths in Toronto in 1921 from venereal diseases than from either cancer or tuberculosis. There are six venereal disease clinics in Toronto, and during 1921 33,322 cases were given treatment.

THE Mexican Medical Association recently celebrated the third anniversary of its foundation, when, in addition to other celebrations, a speech was delivered by Dr. Brieso Vasconcelos, editor of the *Gaceta Médica de México*.

A MEMORIAL to Dr. A. Charpy, professor of anatomy in the University of Toulouse, has been erected by the Faculty of Medicine of the University.

ACCORDING to a recent census there are at present 22,990 medical practitioners in France, of whom 5,415 are in Paris and 17,575 in the departments and colonies. There are thus four times as many doctors in proportion to the population in Paris as in the departments.

DEATHS from acute alcoholism in New York have increased this year 27 per cent. over last year and 89 per cent. over 1920, according to the records of Dr. Charles Norris, chief medical examiner. These figures include only those persons who died without medical attention, and Dr. Norris considers that many others attended by private medical practitioners have died from the same cause.

WE have received a copy of a pamphlet, *Torquay Marine Spa*, issued mainly to set forth the facilities for treatment provided by the Corporation Medical, Electrical, and Turkish Baths, which were reconstructed in 1914, and have been kept up to date. A great variety of baths can be obtained, and with regard to the selection of those suitable to any particular case, medical men practising in or near Torquay are prepared to advise. The pamphlet also contains a general account of Torquay and its climate. Copies can, we understand, be obtained from the General Manager of the Baths.

THE death is reported of Dr. J. K. A. Wertheim Salmonson, professor of neurology and radiology at the University of Amsterdam, on September 16th, at the age of 58.

THE first woman medical student in Turkey has recently been registered at the Constantinople faculty of medicine.

THE available life tables in the United States for the year 1920 show that there has been an increase of 2.75 years in the life span in the last twenty years (1901 to 1920). The expectation of life at birth in the United States is said now to be 54.3 years, while in 1910 it was 51.5, and in 1901 49.2. In the last two decades there has been added five years to the expectation of life, and the span of life has been lengthened by a fifth in one generation.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 422, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 422, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Attilio*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medicera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Dacifus, Dublin; telephone, 4737.
4. Intendant Square, Edinburgh.
5. telephone, 4361, Central.

QUERIES AND ANSWERS.

SCHLATTER'S DISEASE.

"W. G." writes: I have under my care what I believe to be a case of Schlatter's disease—epiphysitis of the knee-joint. I have tried to find references to its pathology, etc., but so far without result. Can you give me any assistance?

"Schlatter's disease" is the name given to avulsion of the tubercle of the tibia. The following references will be found to supply all the most recent information on the subject: *Brit. J. Clin. Chir.*, 1920, exx, p. 319 (this is the best and gives fullest bibliography); *J. Orth. Surg.*, 1921, lii, p. 550; *Norsk Mag. for Lægevidenskaben*, 1921, xxxii, p. 320; *Chirurg. degli Organi di Morim*, 1921, v, p. 353; *Annal. Surg.*, 1921, lxxlii, p. 77; *Lancet*, 1921, i, p. 482.

MCINTYRE'S, BUSK'S, AND WINCHESTER'S SPLINTS.

"IGNOTUS" would like to know if some correspondent of the JOURNAL could kindly inform him where any published reports of the splints devised by Professor Busk and Mr. Winchester can be found. They were mostly modifications of McIntyre's leg-splint and Desault's and Liston's long splint. The works of McIntyre and Desault are to be found in medical libraries in London, but Busk when he practised surgery wrote very little, though after taking up anthropology he wrote much that is of permanent scientific value. Mr. G. W. H. B. Winchester died in 1901, leaving no well-known writings.

ASTHMA.

DR. THOMAS MARTIN (Peebles) writes: I have a patient, an adult, who has suffered from severe asthma for two years since the removal of nasal polyp, previous to which she had no attacks. All the usual remedies have been used unavailingly. Vaccine treatment in an institution was a failure. Adrenaline gives great relief during the night. Any suggestions would be welcomed.

INCOME TAX.

Motor Car Transactions.

"J. W. M.," "J. M. L.," and "H. W. F."—The principle underlying the question of motor car renewals is this—that the car with one of similar grade, power, is a legitimate expense, but to the extent to which the expenditure provides an improvement in car equipment the expense is not legitimate. A corollary, which is official evidence given before the Tax, is that if the above condition is allowable even though it involves a net cost.

- "H. W. F." £400 — £110 = £290, assuming the car to be similar.
 "J. M. L." £195 — £75 = £120, on the same assumption.
 "J. W. M." £560 — £180 = £380.

LETTERS, NOTES, ETC.

EPIDEMIC STOMATITIS.

DR. W. A. TRUMPER (Ivybridge) writes that the cases referred to by "Cloybank" (p. 537) reminds him of two children at a mill-house in the Kennet valley over twenty years ago who had similar signs and symptoms. "An inquiry as to the drains caused the parents to pour some carbolic acid down those channels. The following day their tea tasted of carbolic, and the diagnosis was a polluted well. Possibly 'Cloybank's' cases may have a similar cause."

THE GENERAL PRACTITIONER AND REFRACTIONS.

DR. CHARLES J. HILL AITKEN (Kilnhurst, nr. Rotherham) writes with reference to Dr. Larking's letter (p. 534): If a medical man is competent to do refractions let him have the necessary plant for the work visible in his surgery and the natural curiosity of his patients will soon let it be "known" that he is prepared to examine for and prescribe spectacles. After a few successful cases a "suitable title" on his plate will be quite unnecessary.

THE CARE OF THE TEETH.

DR. A. D. JILLA, L.M.S. Bombay (Manchester), in the course of a letter on this subject, writes: From personal experience and daily contact in practice I find that men and women are not inclined to devote even one-tenth of the time to their mouth and feet that they give to their face, hands, and hair. It is important to use the toothbrush the first thing in the morning, but perhaps the toothbrush itself may be the stumbling-block. It is not easy to design a toothbrush that would conveniently make its way between the teeth and the cheek up to the very last molar. Some toothbrushes are too hard. They make the gums bleed and are prejudicial to the safety of the enamel of the teeth if roughly used. Some are too soft, or get so by use. Moreover, the cost of the toothbrush is, in an average family of working and middle classes, an ever-recurring item. In countries the teeth of whose inhabitants are a source of envy to Western nations it is hardly the toothbrush that is responsible for the elegant condition of the teeth; it is mainly the general desire and instinct—scrupulous as well as religious—of oral hygiene. In India the Hindus of certain districts use slender twigs of the babul tree every morning with which to brush their teeth. They chew it first and make the ends brushlike. A fresh one is used every day by each individual of the family and thrown away afterwards. But the rest of the people use their index fingers with a little tooth-powder—ordinary ashes or fine charcoal-powder. Custom, as well as religious injunction, forbids every Indian to taste any food or drink in the morning without this necessary mouth toilet and the morning prayers subsequent to the toilet and ablution. In my opinion the teeth of Western people stand poor chances of real improvement and trim condition as long as they stick to the idea of the tooth brush. Nature has supplied us with a very pliant elastic tooth brush in the shape of the first or index finger. It can not only work its way to the farthestmost molar tooth, but it also feels its way, using less force when any of the gums happen to be in an inflamed condition, or any of the teeth loose or painful. The finger can be used horizontally or vertically, as some dentists recommend for the toothbrush, and the nail is also handy to reach the clefts and interspaces between the teeth.

Education on oral hygiene to school children is indeed a good recommendation, but unless the parents co-operate, and the teachers inform them regularly immediately they notice anything wrong about the condition of the children's teeth, I am afraid no satisfactory result could be obtained. But perhaps the guilt should be laid at the door of the teachers and the parents themselves in the first instance. These should therefore be initially approached by suitable propaganda, and, above all, let them begin with the index finger themselves in the start.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 32, 33, and 34 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 30 and 31. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 124.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 422, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

Orders of the Post Office to receive postage in initials or numbers.

MEDICINE.

202. A Symptom of Tumour of the Middle Cranial Fossa.

A. v. SARBÓ (*Klinische Wochenschrift*, August 5th, 1922, p. 1597) describes a symptom which he regards as a valuable indication in the diagnosis of tumour affecting the middle cranial fossa and especially the mid-brain. This symptom consists in a peculiar reeling backwards when in the standing position. The upper part of the body is bent backwards first, and reeling backwards follows. To the symptom the author gives the name of "hypotokinesis." The patient stands with his feet together, the examiner raises the patient's head by the chin, so that the neck is bent backwards; if reeling does not occur, then the patient is told to close the eyes. When hypotokinesis or reeling backwards is well marked, retropulsion also occurs. The author records three cases in which, in addition to other symptoms of brain tumour, reeling backwards (associated later with ataxia in two of the cases) was a prominent symptom. In one the growth was in the mid-brain (left corpus mammillare); in two the growth extended to the mid-brain, though commencing in other parts. The author has observed this symptom, hypotokinesis, in certain cases of epidemic encephalitis, in paralysis agitans, in endoarteritic circulatory disturbances or softening in the corpus striatum, in tumours of the mid-brain (corpora mammillaria, pineal gland, corpora quadrigemina, optic thalamus, around the third ventricle) and in tumours arising in other parts but compressing the mid-brain; also in hydrocephalus with distension of the third ventricle. The author considers the hypotokinesis and the ataxia to be the results of affection of the red nuclei (of the tegmentum of the crura cerebri) and of the fibres connected with these nuclei. He considers the maintenance of static equilibrium to be the function of the red nucleus and its fibre system. Disturbance of equilibrium is a characteristic sign of disease of the mid-brain. At first (whether the disease be encephalitis, or tumour, or circulatory disturbance or softening) the disturbance of equilibrium is shown by hypotokinesis; as the disease advances greater disturbances of equilibrium occur—retropulsion and ataxia.

203. The Therapeutics of Quinidine.

P. LEREBoullet and JEAN HEITZ (*Paris Médical*, July 1st, 1922, p. 7), in their annual review of diseases of the heart and blood vessels, discuss the therapeutics of quinine and quinidine in cardiac irritability. Quinidine is an isomer of quinine, than which it is more soluble and has a greater tonic effect on the cardiac muscle; it diminishes cardiac irritability, acting in an entirely different way from digitalis, adrenaline, etc. It suppresses auricular fibrillation and counteracts certain drugs which produce fibrillation. Quinidine diminishes the contractility of cardiac muscle fibres, and in the end paralyses them; it reduces the conductivity of the bundle of His. In large doses it is said to paralyse the pneumogastric centres in the medulla and then the peripheral nerve endings. Arterial pressure is lowered by experimental injections of quinidine. In a large number of cases of complete arrhythmia quinidine restores the normal rhythm in a very short time. The majority of writers have been more successful in recent cases of arrhythmia than in those in which it has existed for some years. Some authors have found that complete arrhythmia returns in a few days or even in a few hours. The authors recommend that the drug should be administered for some time in small doses in order to prevent the return of arrhythmia, and they cite a number of cases recorded by various observers in which this was successful. The dosage employed by different writers varies greatly. Frey recommends a daily dose of 0.2 gram at first, and has never exceeded 0.8 gram, while Jenny has given 3 grams per diem; the latter author records the highest proportion of successes. Some cases of intolerance occur even after smaller doses have been taken. The normal rhythm is usually restored suddenly, sometimes without the patient being conscious of it. The pulse rate often falls to 54-60, but a few auricular extrasystoles, recurring more or less regularly, are often observed. It would appear that quinidine acts better in those cases in which moderate doses of digitalis have previously been given. Schrumpf alone advises that the two drugs should be given simultaneously, but Hewlett and Sweeney have observed the Stokes-Adams syndrome in such cases, and it is recommended that caffeine or camphor should be substituted if a cardiac tonic is considered necessary.

204.

Encephalitis Lethargica.

GASBARRINI (*Archiv. di Patolog. e Clin. Med.*, June, 1922, p. 353) discusses at some length the phenomena of encephalitis lethargica. He describes the classical features of the disease, giving a detailed analysis of the various symptoms and points out the chief clinical data which serve to differentiate this disease from other affections. He thinks there has been too much division of the disease into a number of different types. On the whole, he believes encephalitis lethargica has no direct relation with influenza. Dubini's electric chorea corresponds to the myoclonic form of encephalitis. There is some ground for believing that epidemic hiccup is a form of encephalitis. According to the predominance of certain symptoms the disease may be of a somnolent type, a myoclonic, a polynuritic, or more rarely a hyperkinetic variety. The course of the disease may be acute, subacute, or chronic, lasting for months or years. Oscillation and relapses are not uncommon. Amongst the sequelae the author draws special attention to the Parkinsonian symptoms, the pseudo-paralysis agitans, and to the inversion of the rhythm of sleep and wakefulness, so that night is turned into day. Mortality varies very much—5 to 55 per cent. So far no therapeutic means has been found to cure the disease.

205.

The Treatment of Diabetes Mellitus.

ELLIOTT P. JOSLIN (*Boston Med. and Surg. Journ.*, June 22nd, 1922, p. 833) refers to the fact that the average known duration of fatal cases of diabetes in the period 1895-1913 was 3.3 years (Boston City statistics) and that in 1920 the duration was 5.3 years. He gives four tables showing his own results, which confirm the general experience, and observes that in the first decade of life the duration in these cases has exactly doubled. "The needless mortality in diabetes is greater than we realize." "Diabetics seldom die of their disease *per se*, but of complications which are largely preventable—coma, gangrene, infections." The marked reduction in the diabetic death rate in hospitals is, he considers, almost entirely due to the prevention of coma. Nearly all these deaths occur when the patient's diet is suddenly changed. It should be an absolute rule in severe, long-standing, complicated, obese, and elderly cases, and in all cases with acidosis, to make only gradual changes in diet. Nearly all these cases can be traced to over-feeding with fat and restriction of carbohydrate. The author states that in the larger hospitals in Boston the danger of ether as an anaesthetic for diabetics has led to its replacement by nitrous oxide and oxygen. Diabetics should always be warned of the danger of gangrene following minor injuries if they become infected. Table V gives "Diabetic diet cards, with composition of essential foods," the author explaining his system of "test" and "maintenance diets." Calorie values are of importance, as a continued low caloric diet causes nearly all patients to become sugar-free. The rationale of treatment should be explained to patients from the beginning. Acidosis may be largely prevented by "Shaffer's formula," which shows that alkalis are needless and that the carbohydrate-fat ratio should be regulated in accordance with actual metabolism. Newburgh and Marsh have shown the necessity of the patient receiving sufficient calories. The author states that obesity preceded diabetes in fully 75 per cent. of 1,000 of his cases, and that 66 per cent. admitted excess in food. He recommends systematic routine examinations and regular instruction. An excess of blood sugar may warn the physician before sugar appears in the urine.

206.

Vaccines in Influenza.

F. BLOCK and others (*Hygiea*, June 15th, 1922, p. 467), constituting a committee of inquiry, report on the therapeutic experiences gained in Sweden and elsewhere during the recent epidemics of influenza. They have little good to say of the numerous drugs, including alcohol, experimented with in influenza, but they have come to the conclusion that inoculation with the products of streptococci, pneumococci, and Pfeiffer's bacillus is of considerable value in preventing the complications of influenza. In Sweden the vaccine distributed was streptococcal and pneumococcal, and of the sixty-five physicians who sent reports on their experiences with vaccines to the Board of Health, forty-one claimed to have obtained strikingly good results, the course of the disease being rendered more mild, and the frequency of complications being reduced. The results obtained in the Swedish army by inoculations in November, 1918, pointed in

the same direction. This procedure has proved to be perfectly harmless, but it is probable that the immunity conferred is of comparatively short duration, and may not last for more than about three months.

207. Interpretation of the Wassermann Reaction.

WALLENSTEIN (*New York Med. Journ.*, May 3rd, 1922, p. 514) discusses the reliability and limitations of the Wassermann reaction, pointing out the importance of correctly interpreting the results of the test, which for all practical purposes may be regarded as specific, indicating the presence of spirochaetes somewhere in the body, with the few exceptions of yaws, leprosy, malaria, and scarlet fever. A doubtful reaction in early or late latent cases must be regarded as positive, but, although insufficient for the diagnosis of syphilis in the absence of symptoms and a history of infection, a doubtful reaction accompanying a suspicious primary lesion is confirmatory. A negative reaction is of no value in eliminating syphilis when a primary sore is suspected, but it is of great value when suspicious secondaries are present, and syphilis can only be excluded when a negative result persists for several months, and the same is the case in suspected tertiary lesions. In treated cases a negative reaction is necessary for at least a year before a cure can be pronounced; during that time there must be absence of symptoms and the spinal fluid must also be negative. The intensity of the reaction in the various stages of the disease is of value in prognosis, persistently positive reactions being indicative of visceral or nervous syphilis, and usually pointing to grave infections. Contaminated blood may give falsely positive reactions, and a positive reaction may be obtained shortly after general anaesthesia or in blood containing bile, while the ingestion of alcohol for two days prior to taking the blood will render the reaction negative. In a suspected case eight consecutive daily tests should be made, since a single negative reaction means nothing. A positive reaction with the cholesteryl antigen only, or by the ice-box method of fixation, is of value in treated cases only with a history or symptoms of syphilis.

SURGERY.

208. Some Causes of Amaurosis in Infants.

R. F. MOORE, B. T. LANG, H. NEAME, and P. G. DORRIS (*Brit. Journ. Ophthalmol.*, August, 1922, p. 337). In their report to the Committee of the Lang Research Scholarship, based upon sixty cases, give the results of investigations of all possible causes affecting the sight of infants. All the cases when first seen had defective vision, some presenting temporary amaurosis, others becoming mentally defective, and a close relationship existed between delay in the development of the fixation reflex and the presence of albinism. Each feature is reported upon independently, with notes of illustrative cases. The absence of the light fixation reflex in infants with otherwise normal eyes is frequently an early sign of future mental deficiency, as evidenced by such signs as delay in holding up the head, development of speech, etc., and delay in the appearance of the reflex is often associated with a pigment deficiency affecting the retina and choroid, but in such cases the light fixation is only delayed and appears in due time. The reaction of the pupils to light was only absent when there was a definite disease of the optic nerve, and all the cases of temporary amaurosis and of mental deficiency showed an intact pupillary reflex arc. Only seven of the series afforded evidence of congenital syphilis, in four of which choroido-retinitis was present with, in one case, considerable opacities in the vitreous. Consanguinity of the parents (three cases), difficult labour (ten cases), and premature birth (five cases), did not appear to have any particular otiological relation to the condition, and the presence of eye-rubbing, head-nodding, ystagnus, and squint usually pointed to a defect in the eyeball, such as cataract, refractive error, or pigment deficiency. Albinism affecting the retina and choroid was present in seventeen cases, associated with nystagmus in all but three, in whom fixation never properly developed. An analysis of these sixty cases showed the primary cause of amaurosis to be: temporary amaurosis (5), mental deficiency (19), albinism (17), cataract (7), hypermetropia (5), and indus disease (7), in which, however, there was a certain amount of overlapping, as, for instance, mental deficiency being often associated with albinism.

209. Effects of Tonsillectomy on the General Health of Children.

10,000 children on whom tonsillectomy has been performed under uniform conditions, 5,000 have been re-examined by D. KAISER (*Journ. Amer. Med. Assoc.*, June 17th, 1922) one year after operation, and a detailed history of the child's complaints are tabulated before and after operation. Analysis

of the causes for operation shows that obstructive symptoms or evidences of tonsillar infection existed in 99 per cent. of the cases. In 5,000 children re-examined, the greatest improvement came to the group that showed evidence before operation of obstruction and infection. Obviously, a child suffering from obstructive tonsils and adenoids with symptoms of infection should have the benefit of tonsillectomy. Considerable improvement in the child's general health was noted in the group that presented evidences of infection from the tonsil but when the tonsil presented no marked hypertrophy. Undoubtedly this group showed benefit from this operation. No marked change was found in the child's general condition in the group operated on for hypertrophy only. There was less malnutrition in this group. One year is too short a period in which to determine the benefits of the operation to this group. Taken as a group, there was a very decided improvement in the general condition of the children operated on. The nutritional status was improved in many instances. The high percentage of undernourished children one year after operation—29 per cent.—suggests that diseased tonsils are only a small factor in the production of malnutrition. The operative risk is not great, for 10,000 children were operated on without a surgical fatality, and post-operative complications occurred in only a small percentage of the children, assuring reasonable safety if proper care is taken. The ultimate effect of the operation on a child cannot be determined at the end of a year; but at that time 84 per cent. of the children have been considered in better general health, as indicated by their physical examination and analysis of their complaints.

210.

Loose Bodies in the Joints.

POLLIDORI (*La Chirurg. degli Organi di Movim.*, April, 1922, p. 187) publishes a case of loose bodies in the knee-joint and takes the opportunity to refer at some length to the whole subject. Apparently Paré, in 1558, was the first to describe a loose body discovered in opening an abscess of the knee. Loose bodies occurring in healthy joints are usually traumatic in origin. Experimentally it is not easy to produce a permanent loose body by injury, as it tends to become absorbed. Probably a series of injuries is necessary, or some pathological change goes on as a secondary result, and possibly there exists some tendency to their formation in individuals, for injury will not cause a loose body to form in every case. When once formed they may increase in size. In diseased joints they may form in the thickness of the fibrous capsule or subsynovial cellular tissue, from the synovial membrane itself, from the articular cartilage, or as sequestra from the bone as a result of dissecting osteo-chondritis, tubercle, or other obscure cause. A lengthy bibliography of the subject is appended.

211. A Non-surgical Method of Duodeno-biliary Drainage.

M. J. SYNKOTT (*Amer. Journ. of Surgery*, June, 1922, p. 136) describes the diagnostic and therapeutic value of Lyon's method of duodeno-biliary drainage. Infectious play an important part as an underlying cause of chronic ailments. A systematic attempt must be made to locate all focal lesions and eliminate them if possible. Lyon has demonstrated that the gall bladder and bile ducts have frequently been overlooked in the search for infections, particularly in the absence of clinical symptoms referable to that portion of the anatomy. Many chronically infected gall bladders give no local symptoms. To establish early diagnosis and treatment of biliary stasis is most important, because this later means gall stones. Lyon's method is the only way in which a diagnosis can be made in every case. This is based on the fact that a solution of magnesium sulphate, when instilled into the intestine of dogs, produces relaxation of the sphincter of Oddi, with a flow of bile from the common duct. The duodenal tube is swallowed and the stomach washed out. The patient then lies down and the tube is swallowed to the 75 cm. mark, when the metal tip is in the duodenum. The magnesium sulphate solution is then introduced and the bile specimens obtained by aspiration, and cultures taken. The specimens thus obtained are studied chemically and bacteriologically, whilst all possible precautions are taken against contamination. Finally, transduodenal lavage is performed, consisting of the instillation of Ringer's solution into the duodenum, after which the tube is removed. Vaccines are later prepared and the patient immunized against the infecting organism, and other treatment adopted as appears indicated. The Lyon technique offers a rational plan of treatment, the undoubted value of which is proved by a constantly increasing mass of clinical evidence.

212

Post-operative Acetonuria.

T. LAURENTI (*Il Policlinico*, Sez. Chir., May 15th, 1922, p. 282) examined the urine for acetone of 160 cases, 85 of which were men and 75 women, on whom various operations had been performed under chloroform, ether, local anaesthesia with 0.5 per cent. novocain, and spinal anaesthesia

with a mixture of 4 per cent. novocain and 2 per cent. stovaine. The results were as follows: (1) Post-operative acetouria was almost constant in spinal anaesthesia (84 per cent.), chloroform narcosis (81 per cent.), and much less frequent in local anaesthesia (15 per cent.). (2) The duration of the phenomenon varied on the average from two to five days. It was rarely as long as six days, and in only one instance lasted till the seventh day. (3) The presence of acetouria did not in any way affect the post-operative course of the case. (4) The nature of the disease and the character of the operation were of no importance in the pathogenesis of acetouria. (5) While sex had no etiological significance, the age of the patient was of some importance, as the reaction was most intense in young persons. (6) The fluid diet which was given to all the patients for from three to eight days after the operation was also a factor, as the phenomenon almost always disappeared when normal diet was resumed. (7) Rise of temperature, which occurred in the first twenty-four to forty-eight hours after the operation, especially after spinal anaesthesia, had no effect on the appearance of the acetouria. (8) The degree of acetouria was always directly related to the nature of the anaesthetic, and was not connected with the character of the operation. (9) The operative trauma in itself was essentially the determining cause of the acetouria, as it developed after the operation, but was not influenced by its nature, the nervous system of each individual reacting differently to stimuli.

213. Dupuytren's Contraction.

TRIGAT (*Le Scalpel*, June 17th, 1922, p. 569) reports a well-marked case of Dupuytren's contraction operated upon with complete success five years ago by thorough removal of the palmar aponeurosis. None of the other methods (partial excision, fibrolysin injections, electricity, etc.) gives permanently satisfactory results. In this patient the result, as judged by the photograph taken five years after operation, is perfect, and the man is able to do his work as an egg merchant without drawback. Early massage and exercises are indicated.

214. Non-success in Spinal Anaesthesia.

DI PACE (*Rif. Med.*, May 20th, 1922, p. 508) has examined one of the factors to which non-success in spinal anaesthesia has been attributed—namely, admixture of blood in the cerebro-spinal fluid. He concludes that in the small proportion of blood no cause of failure can be found, and that the presence of blood is a mere coincidence. He bases his conclusion on clinical experience—for example, a hysterectomy was done under spinal anaesthesia with stovaine dissolved in sanguinolent cerebro-spinal fluid, using a thick needle with a defective point, conditions all said to be a cause of failure, and the anaesthesia was complete. Stovaine injected directly into the blood produces its ordinary effects, showing that blood does not destroy its power.

OBSTETRICS AND GYNAECOLOGY.

215. Uterine Haemorrhage of Benign Origin treated by Radium.

AN analysis of 527 cases of myoma uteri and other benign lesions causing uterine haemorrhages which have been treated by irradiation is presented by J. G. CLARK and F. E. KEENE (*Journ. Amer. Med. Assoc.*, August 12th, 1922, p. 546). In 476 cases, which required only one treatment permanent amenorrhoea occurred promptly, or after a short interval of temporary amenorrhoea there was a return to normal when the dosage had been intentionally light with this end in view. Of 433 cases, 40 either required a second application of radium, or an operation was necessitated on account of a persistent flow. The actual percentage in which the bleeding was controlled by the first application of radium in 476 cases was 91. In this whole number only one death occurred, and this was of obscure origin. In 47 cases bleeding recurred after the application of radium; in 27 several months after the treatment. The recurrence was slight, or the periods returned to normal and did not require subsequent treatment, in 23 cases. Menopausal symptoms seldom if ever occur in young women when a dosage of 50 mg. is applied for from six to eight hours; and in no case has the climacteric been induced by this dosage. Larger doses will produce these symptoms. The age factor in its relationship to the menopause is not nearly so much to be taken into account as the temperamental and nervous factors. In the total number of cases in which radium has been used five women subsequently became pregnant. It is evident that the application of radium gives but little forecast in favour of restoring the child-bearing possibilities; for of these pregnancies only two children came to full maturity. This study,

therefore, emphasizes the statement already made that when pregnancy is still in contemplation by the patient an operation should be advised, instead of irradiation. The criticism offered as to the use of radium has been that the final results of irradiation are not yet known. In at least 300 cases that have been followed from three to six years, so far no single instance has come to the attention of the authors in which there was any remote deleterious result which could in any way be traced to radium. A reapplication was necessary for the relief of a continuation or a recurrence of the abnormal bleeding in 23 cases. In all of these the condition was cured by a second application except in two, which required operation. Of the 527 patients, 18 were operated on subsequent to irradiation. Fourteen of these were myomatous cases in which the bleeding persisted or recurred more or less profusely, following a variable period of amenorrhoea. Four patients were subsequently operated on for chronic pelvic inflammatory disease and one for haemorrhage. In the 14 patients requiring a subsequent operation, 10 of the operations were for myomata of the larger submucous type, 3 for myopathic haemorrhage, and one, in which there was recurrent bleeding from a cervical stump after a hysterectomy, for an adenomyoma. In the entire series there was but one death, which occurred from peritonitis a few days after an extensive plastic operation and an application of 50 mg. of radium for twenty-four hours. Phlebitis occurred in two cases; in one, a mere recurrent symptom of an old phlebitis. In the second, bilateral phlebitis followed a repair of the cervix, a posterior colporrhaphy, and irradiation. Eight patients developed symptoms of more or less severe neuritis. This mode of treatment is not offered as a competitor of surgery; the two go hand in hand, and both must be supervised by the surgeon and not by the x-ray expert or the radiologist, for each, in a varying degree, is a surgical measure. Irradiation is considered by the author to be the treatment of choice for the smaller myomata in women approaching or within the menopausal years whose only symptom is haemorrhage.

216. Radium Treatment of Uterine Myomata.

M. H. VIOLET (*Lyon Médical*, May 25th, 1922, p. 419) is of opinion that although the majority of uterine myomata are unsuited for radium therapy, this treatment has definite indications (1) as a preliminary to operation in patients who have become so anæmic that immediate surgical intervention would be dangerous; (2) in cases of uncomplicated myomata of which the capital symptom is menorrhagia, and in which the patient, although a semi-invalid, is averse to operation. Small myomata, if subperitoneal and pediculated, are best treated by polypectomy; if intramural, by enucleation; and if submucous, by intrauterine exploration and extirpation. Larger myomata in multiparous subjects are suitable for treatment by subtotal hysterectomy. Cervical myomata causing or capable of causing compression phenomena call for total hysterectomy. Surgical operation is clearly indicated when there are signs suggesting coincident adnexal disease, peritoneal adhesions, sarcomatous transformation or degeneration of the myoma, presence of cancer of the corpus uteri, or pregnancy. In cases treated by radium applications, endeavour should be made to graduate the dosage so as to obtain haemostasis and shrinkage of the tumour without necessarily the production of a definitive amenorrhoea. In women aged over 40 Violet finds doses of 7 to 10 "millicuries destroyed" usually sufficient. The case is related, as an example of an ideal result, of a patient, aged 32, who suffered from profuse menorrhagia due to the presence of a myoma twice as large as the fist; after application of 75 mg. of radium bromide for twenty-four hours, corresponding to 7 "millicuries destroyed," the uterus regained its normal dimensions, and as a sequel to eight months' amenorrhoea with symptoms of artificial menopause the menses gradually resumed their normal characters, and signs of ovarian insufficiency disappeared. It is preferable to give small doses, repeated if necessary. Comparatively larger doses will be required if the myoma is of large size; if the uterine cavity is central, and if the thickness of the wall exceeds 2 cm.

217. Post-partum Eclampsia.

ACCORDING to H. THALER (*Zentralbl. f. Gynäk.*, June 24th, 1922, p. 1019), it is rare for post-partum eclampsia to manifest itself later than a few hours after labour. Of 472 cases of eclampsia treated during twenty-nine years at the Vienna Frauenklinik 82 were examples of post-partum eclampsia, and in 4 only was the first convulsion observed to occur later than seventeen hours after labour. Prognosis is more favourable in early than in late post-partum eclampsia: death occurred in 2 of 41 cases of eclampsia manifesting itself within three hours of labour, and in 7 of 40 later cases. Similar findings have been reported from other clinics. Post-partum eclampsia

is especially liable to be followed by severe psychoses, and this is particularly frequent in the cases in which the onset of the eclampsia is late. Thaler's statistics do not confirm those of Seltz in correlating post-eclamptic psychoses with previous occurrence of unusually numerous convulsions. B. BIENENFELD (Ibid., p. 1013), from a study of the literature, has traced records of 14 cases only of the first occurrence of an eclamptic convulsion late in the puerperium—from the sixth to fourteenth day. She records the case of a 2-paræ, aged 32, who after an instrumental delivery at term suffered from severe septic endometritis; on the twelfth day, after an apyrexial interval of six days, vomiting, albuminuria, coma, and convulsions occurred, followed by an acute psychosis. Although slight albuminuria persisted six months later, the case is regarded as one of eclampsia rather than uremia.

218. Sarcoma of the Uterus.

ACCORDING to M. TERNAT (*La Gynécologie*, May, 1922, p. 238), sarcoma of the uterus is from forty to fifty times more rare than carcinoma, and affects five times more frequently the corpus uteri than the cervix. Large sarcomata of the cervix, when ulcerated, are usually regarded as carcinomata, from which they cannot be distinguished except by microscopic examination. Sarcomata may take origin either in the endometrium, in which they are more often of the diffuse than the circumscribed variety, or in the myometrial layer, more often in the connective tissue than in the muscle fibres. Sarcomatous metaplasia of myometria is frequent and should be suspected in myomatous patients in whom metastasis persists after the age of the menopause, in conjunction with an increase in the size of the tumour. Hyaline and mucous degenerations and haemorrhages into the tumour not infrequently supervene in cases of uterine sarcoma and lead to formation of pseudo-cysts, which may attain considerable dimensions and resemble closely ovarian cysts or adenomyomata. Owing to the widespread metastases which occur, prognosis is grave. Clinical experience points to the advisability of performing hysterectomy in cases in which myomata do not undergo well-marked atrophy following the menopause.

PATHOLOGY.

219. The Significance of *B. Paratyphosus B* in the Blood.

A. LEMERIE and J. LEVESQUE (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, July 13th, 1922, p. 1045) report the case of a man, aged 59, suffering from lymphatic leukaemia, who developed an acute lobar pneumonia. On his admission to hospital on the sixth day of disease a blood culture was taken, which showed the presence of *B. paratyphosus B*. The sputum contained large numbers of pneumococci, and there was nothing in the clinical picture of the patient to suggest anything atypical. The temperature fell on the twelfth day, but rose again later as a result of the involvement of the opposite lung. Three weeks after the commencement he was perfectly convalescent. Examination of the patient's serum on the eighth, twelfth, and twentieth days of disease for the presence of agglutinin against his own organism was uniformly negative, while a second blood culture performed on the eighteenth day failed to reveal the paratyphoid bacillus. It would seem doubtful whether, in this case, the bacillus exerted any pathogenic effect whatever. There are a number of cases in the literature in which this organism has been recovered from the blood of patients suffering from such diverse diseases as scarlatina, measles, tuberculosis, cerebrospinal fever, and malaria, without there being any evidence of sufficient weight to incriminate it as playing any causative part in the genesis of the clinical symptoms. There are also cases in which the bacillus has been associated with other organisms, which were apparently the primary invaders, and which had merely paved the way for a secondary paratyphoid infection. The bacillus is widespread, and the authors insist that its presence—even in the blood—in the absence of clinical signs and of confirmatory serum reactions, must not be forthwith regarded as responsible for the origin of the disease.

220. The Effect of Antidiphtheritic Vaccination.

In order to test the immunizing effect of an antidiphtheritic vaccine A. BESSEMAN and P. BORREMANS-PONTHIERE (*Le Scalpel*, July 8th, 1922, p. 653) selected twenty children with a positive Schick reaction, and gave them three injections, at intervals of eight days, of a toxin-antitoxin mixture containing 80 per cent. of the L + dose of toxin. Five months later sixteen of the children were retested for susceptibility, and in order to make the test more rigid they used, not 1/50 minimal lethal dose of toxin, but two doses injected at different points of the arm, one of 1/40 minimal lethal dose, and the other of 1/10 minimal lethal dose.

Control reactions of treated toxin were made on the opposite arm. Thirteen of these children were frankly negative to both injections of active toxin; one was negative to the smaller dose, but reacted to the higher. One other was positive to both, but as this child had only received two prophylactic inoculations it is hardly fair to take it into consideration. Finally, one child which had been fully vaccinated reacted to both doses, showing that its susceptibility had not been sufficiently diminished to render it Schick-negative. Is the failure of this last case to be attributed to an insufficient amount of toxin in the vaccine, or is it dependent on an individual peculiarity of the child in question? This point is one which will only be rightly decided when further work has demonstrated the optimum constitution of the immunizing mixture.

221. The Wildbolz Auto-Urine Test for Tuberculosis.

E. STIEFEL (*Schweiz. med. Woch.*, July 27th, 1922, p. 746) has investigated the behaviour of the Wildbolz test in 400 persons, most of whom were suffering from pulmonary tuberculosis. The test consists of injecting into the patient's skin a small quantity of his urine, concentrated by evaporation *in vacuo*; it is assumed that the more active the disease the greater is the quantity of the tuberculous antigens in the urine. The author controlled this test by simultaneous intracutaneous injections of tuberculin (Mantoux's test). In 206 cases of presumably active tuberculosis there were 173 giving a positive reaction both to the Wildbolz and the Mantoux tests, and 18 giving a negative reaction to both these tests. Only in 4 per cent. was the Wildbolz reaction negative or doubtful, while the Mantoux reaction was positive. Among 143 cases without signs of active tuberculosis, as great a proportion as 28 per cent. gave a positive reaction to the Wildbolz test. A comparison of the severity of the two reactions showed that, with certain exceptions, in severe disease the Wildbolz reaction was as great or greater than the Mantoux reaction, and this comparison can therefore serve as an aid to prognosis. The author concludes that while a negative Wildbolz reaction is strongly presumptive of the absence of active tuberculosis in cases giving a positive Mantoux reaction, a positive Wildbolz reaction is not proof positive of active tuberculosis, for in 28 per cent. of cases of clinically inactive tuberculosis it may be positive.

222. Pathogenic Moulds.

S. G. GREENBAUM (*Journ. of Infect. Dis.*, July, 1922, p. 26) has made a study of the biological properties of pathogenic moulds. He found that the power to liquefy gelatin is a common property of the higher vegetable parasites and varies with the organism, for, although all possess the ferment gelatinase, there is a marked difference in the rate of liquefaction of gelatin by different species. None possess amylolytic ferments, as shown by the fact that no sugar is produced from starch; the fungi grow quite well in 3 and 5 per cent. starch solution, indicating that they can assimilate the larger starch molecule without previous hydrolytic cleavage. The pathogenic fungi do not ferment saccharose, dextrin, glucose, inulinose, maltose, or lactose, and they produce no acids or casein. No indol was produced. Cutaneous affections produced by the higher vegetable organisms are ordinarily not associated with systematic disturbances, but the author has shown that two of the large-spored ringworm fungi and *Achorion schoenleinii* (the fungus of favus) elaborate toxin: fatal to guinea-pigs. After death-marked engorgement of the suprarenals was observed, the appearance resembling that produced by the intraperitoneal injection of diphtheria toxins.

223. *B. Suispastifer* Infection.

A CASE is reported of *B. suispastifer* infection of man in which the organism was recovered by blood culture (J. MacKENZIE; *Journ. R.A.M.C.*, July, 1922, p. 51). The illness began with an acute inflammation of the nasopharynx, which subsided after three days, but was followed by a relapse accompanied by high temperature, pains in the back, and slight bronchitis. Blood culture yielded an organism which obviously belonged to the paratyphoid-enteritidis group, but which, when first isolated, failed to agglutinate with any of the standard serums. After prolonged subcultivation, however, it agglutinated with *B. paratyphosus B*, *B. paratyphosus C*, and *B. aertrycke* serum. It differed from these organisms in its fermentation reactions when the complete set of sugars was inoculated, but behaved exactly like *B. suispastifer*. Agglutination absorption tests suggested *B. suispastifer*. The organism was pathogenic for rabbits, producing some enlargement and mottling of the liver, resembling a "nutmeg" liver. It is generally held that there is no authentic and conclusive record of a *B. suispastifer* infection in man, and this is the first case in which a bacillus showing such reactions has been recovered from the blood of man.

NINETIETH ANNUAL MEETING
OF THE

British Medical Association.

Held at Glasgow, July, 1922.

PROCEEDINGS OF SECTIONS.

SECTION OF OBSTETRICS AND
GYNAECOLOGY.Professor EWEN J. MACLEAN, F.R.S.E., M.D., F.R.C.P.,
President.DISCUSSION ON
STILLBIRTHS AND NEO-NATAL DEATHS.

PRESIDENT'S INTRODUCTORY REMARKS.

IN opening the discussion, the PRESIDENT said that the national importance of the subject only needed to be mentioned to be accorded. Fertility was the index of the present and the earnest of the future prosperity and strength of a nation. Presumably it was for this reason that the law of the land claimed to punish with maximum penalties certain kinds of interference with pregnancy and negligent clinical practice. He thought that presumably even the contraceptionists would approve of their objective, though it seemed anomalous from the national point of view that their propaganda, whether by peer or peasant, in church congress or at the street corner, should be allowed to proceed unhampered. So far as the population of the country was concerned the requirement might arise in the not distant future for the law to develop an ante-conceptual in addition to a post-conceptual application. He thought they might proceed, however, without apprehension of the law to the consideration of their subject. The officers of the Section had been very fortunate to secure the services of the distinguished workers whose names appeared on the programme.

I.—ANTE-NATAL, INTRA-NATAL, AND NEO-NATAL
DEATH:CAUSES, PATHOLOGY, AND PREVENTION, WITH SPECIAL
REFERENCE TO ANTE-NATAL DEATH.

BY

J. W. BALLANTYNE, M.D., F.R.C.P.E.,

Physician in Charge of the Ante-natal Department of the Edinburgh Royal Maternity Hospital; Lecturer on Midwifery and Gynaecology (to Women Students) in the University of Edinburgh; etc.

The Discussion of 1888.

It is a coincidence that thirty-four years ago (in 1888), when the British Medical Association last met in Glasgow, the Section of Obstetric Medicine was occupied with the subject of Intrauterine Death.¹ The discussion was opened by Professor (afterwards Sir Alexander) Simpson of Edinburgh; and those who took part in it were Dr. Barnes of London, Dr. (afterwards Sir John W.) Byers of Belfast, Dr. Fordyce Barker of New York, Dr. Parvin and Dr. H. P. C. Wilson, both from the United States, Dr. Anst Lawrence, Dr. Arthur W. Edis and Dr. Amand Routh of London, and the President of the Section (Dr. More Madden). All these men with one exception have passed from us, but the problem they were then striving to solve is now committed to us: *quasi cursores vitæ lampada tradunt*, and their torch is in our hands to keep alight and to pass on to those who follow us. The present speaker was not present at the meeting referred to; but he was Assistant at the time to Professor Simpson, and it is perhaps significant that it was in that year that he began his researches into foetal diseases and monstrosities.

In one sense the discussion of 1888 had a more restricted range; it did not touch intra-natal death or neo-natal death, and so when Professor Simpson came to the subject of prevention he found himself limited to the consideration of mercury for syphilis, iron for maternal anaemia, diet for albuminuria, curettage for placental disease, potassium chlorate for recurrent foetal death or premature labour, and induction of premature delivery when in previous pregnancies the unborn infant tended to perish in the last weeks. Other speakers suggested the use of the tincture of *Viburnum prunifolium* in cases of recurring abortion from "irritable uterus,"

the correction of uterine displacements, the use of a spare diet and active exercise in instances of perversion of maternal nutrition, and the treatment of constipation. The giving of antisyphilitic medicines to the father was emphasized by Simpson; Edis was far-sighted enough to foresee the need for attention to numerous details in the pregnant woman and the giving to her the same care that a breeder bestowed upon his brood mares; and Routh referred to the detection and treatment of cases in which there was a slight degree of albuminuria. It is a noticeable fact that although Professor Simpson described fully and, making allowance for the lack of numerous observations, very thoroughly the pathology of intrauterine death, none of these who took part in the discussion followed him into this difficult and obscure field of research and speculation. He divided the causes of intrauterine death into (1) foetal, (2) maternal, and (3) placental; and he subdivided the placental into (a) neoplastic degenerations, (b) nutritional changes, including inflammations and degenerations, and (c) apoplectic changes.

The promoter of the discussion and those who took part in it were all men in the front rank of the profession in Britain and America. It may be concluded, therefore, that the occasion elicited the best and the most advanced thought on the subject of intrauterine death then in being. Further, there were recognizable in embryo, so to say, many of the advances in pathology and treatment which have since become so important. Yet it is not difficult to see the limitations of the subject as they then existed. There was no suggestion that it might be well that there be a co-ordinated and systematic investigation of the matter by observers working along similar lines in different centres; the idea of supervising all pregnant women in the interest of the few who were in danger of giving birth to dead infants was absent; treatment, although it was termed preventive, was recognized as beginning after the woman had been delivered of a stillbirth, and it was applied to later pregnancies; and, speaking generally, the individuality of the foetus in respect of its pathology was hardly realized. Further, in respect of syphilis, the typical cause, so to say, of *intrauterine death*, some fifteen years had still to elapse before the discovery of its causal spirochaete, and still longer before the coming of the Wassermann test and salvarsan and its wonder-working substitutes. As has already been noted, there was no reference at all made to death arising in the process of labour (intra-uterine death) or in the early days of life from causes arising in the uterus, but becoming effective only after birth (neo-natal death). Finally, in 1888 there was not even the suggestion of notification, far less of registration, of stillbirths and abortions; consequently their frequency was pure conjecture.

Ante-natal and Post-natal Death.

Before reference is made to details there is one general consideration which calls for attention if the subject of discussion is to be intelligently approached; it deals with the fundamental difference which exists between death in an organism which is fully alive, such as a child or an adult, and death in an organism, such as a foetus, which is less obviously so. It is extraordinarily difficult to express this difference clearly, and yet it is extraordinarily important that it be done. One of the chief hindrances to clear definition is lack of exact and appropriate terminology. The phenomena of ante-natal and post-natal life are in certain respects different, and yet the same words are used or are attempted to be used to describe and define them. For instance, a newborn infant breathes, and so, too, does an unborn infant; but it requires only an instant's thought to convince the thinker that ante-natal breathing is a very different physiological process from post-natal breathing.

After birth respiration is a gaseous interchange between the atmospheric air and the blood as they circulate in the lungs; in the foetal state respiration is a gaseous interchange between two liquids, the maternal and the foetal blood, as they circulate in the placenta. The one is pulmonary, the other is placental; the one takes place via the nose, the other via the umbilicus; the former is practically the only function of the lungs, the latter is one of several functions performed by the placenta. The chief difference, however, is that post-natal respiration is aero-sanguine and that ante-natal respiration is sanguineo-sanguine. Of course the oxygen that the foetal blood receives from the maternal has come in the first instance from the atmosphere through the mother's lungs; but this does not really alter the contrast between the two circulations. In both cases the same term, respiration, is employed, and unconsciously in our thinking we transfer our

knowledge of post-natal pulmonary respiration to ante-natal placental respiration, thus darkening thought when clarity is essential. It will not quite meet the difficulty if "respiration" be reserved for the post-natal and pulmonary function, whilst "aeriosis" is the term applied to the equivalent ante-natal and placental function; for aeriosis unfortunately suggests the presence of air, the very suggestion that is to be avoided. One is not even justified in speaking of them as equivalent functions at all. The importance of these distinctions is manifest the moment that one begins to discuss the causes of ante-natal death, and as soon as one asks, How does a foetus die of suffocation? To many the picture of intrauterine suffocation from, say, a knot on the cord or a large haemorrhage into the placenta is that of an adult with the murderer's hands on his windpipe or with fumes of gas in the room; it is not necessarily the same, and in all probability is vastly different.

What has been said of the contrast between ante-natal and post-natal respiration may also be said, although the contrast is not so dramatic, of ante-natal digestion, excretion, hepatic action, and the corresponding fully developed functions after birth. It is necessary to alter the quality of one's concepts when thinking of these physiological processes as they occur before and after birth. Yet the same terms are applied indiscriminately. Confusion of thought results and fallacies easily creep in. It is as when a man accustomed to read modern English in roman type takes up an Early Middle English work printed in black letter; all the words are unfamiliar to his vision and some of them are unknown by his mind. In thinking of ante-natal phenomena, whether they be of life or of death, one has to be constantly watchful, intent, and prepared as it were to translate from one language into another. To do so with accuracy may, in the present state of our knowledge of ante-natal matters, be barely possible; but such a book as Dr. Feldman's *Ante-natal and Post-natal Child Physiology* will be of great service in preparing the way for exactness.

Special watchfulness in dealing with the problem of foetal death from suffocation—for example, in intra-natal asphyxia—is required. This is no matter of mere academic interest; it deserves close attention. One is sometimes apt to think of life as beginning at birth with the child's first breath: this, of course, is biologically quite erroneous. If a *terminus a quo* for individual existence is insisted upon, it must be found in the moment when the head of the sperm fuses with the nucleus of the ovum, and the zygote steps, so to say, upon the stage. A more common mistake is made when one regards the life after birth as a continuation with identical characters of the life which has gone before, and when one uses such a phrase as to resuscitate, reanimate, or restore the asphyxiated infant. As soon as the infant uses his lungs after birth he is alive in a new way; he was animate in the uterus, he is animate now, but the form or quality of his animation is different; he breathed then through his placenta, he breathes now through his lungs, and his other functions have similarly, although less obviously, undergone a change. For this passage from one form of vitality to another the writer proposed some years ago the word "transanimation," and he offers it again as worthy of adoption; it is not perfect, but it offers it again as worthy of adoption; it is not perfect, but it will serve to mark that there is a difference between the two forms of life. Under this new nomenclature one trans-animates an asphyxiated newborn infant; one does not reanimate, restore, or resuscitate him. He is encouraged to pass over from one form of animated existence to another which is different in quality.

An appreciation of this fundamental difference between the life before and that after birth would have prevented some awkward misunderstandings in the use of such terms as stillbirth, apparent death, etc. In England, and recently in Scotland also, a stillbirth is simply a deadborn infant; but that was not always its meaning even in England. It is one of the few flaws in the magnificent *New English Dictionary* that it gives no other meaning than "deadborn" for "stillborn"; it gives no other meaning than "deadborn" for "stillborn"; the very first illustrative quotation reads, "restoring children to life which were stillborn." Dr. James Blundell was professor of obstetric medicine at Guy's Hospital; in his work published in 1840 he had many passages showing that he did not regard "stillbirth" as synonymous with "deadbirth." On page 112, for instance, this sentence occurs: "The accoucher will sometimes find that children are stillborn, as it is called—that is, although they are not dead, they do not cry, or manifest other indications of life." Blundell refers frequently to the resuscitation of stillborn children, and one regrets that the widespread usage of his time has been

departed from. The word "stillborn" very accurately describes the state of the foetus who has not begun his post-natal life and yet who has not passed through death's portals; he is born, but *lies still*; nevertheless, he may be capable of transanimation. It is perhaps too much to hope that the word "stillbirth" should have its former meaning restored to it, for its identity with "deadbirth" has been stereotyped by the Central Midwives Board of both countries; but such a restoration of meaning would aid in simplifying the understanding of many phenomena of life about the time of birth. In the present discussion it is employed in its official sense of "deadbirth."

Causes of Stillbirths and Neo-natal Deaths.

From the standpoint of causation it is useful to look at early deaths under the three headings of ante-natal, intra-natal, and neo-natal; for each of the three groups thus established has a character peculiarly its own.

The group of causes acting in the ante-natal period of life is the most difficult of comprehension and statement. In chronological order it consists of a germinal, an embryonic, and a foetal time; and in each of these times death to the new organism may happen. Little is known of germinal deaths. A French writer (Vernet) long ago expressed himself somewhat epigrammatically thus: "*L'enfant fécondé jouit de la vie, sujet par conséquent aux maladies, à la mort*," or, as we might render it, "The zygote gloriously exults in life, and so meets maladies and death itself in strife." In the very springs of life there is the possibility of death; but of the etiology of such death there is much ignorance. One expects that the great cause must be something transmitted to the zygote by one or other of the contracting parties, the ovum and the sperm. Some toxic condition of the parents, the impact of some racial poison such as alcohol or lead, may deprive the ovum of the power of going far as an independent organism or may weaken the sperm's embryogenetic effect. Professor Arthur Robinson, in his Sir John Struthers lecture (December, 1920),² has investigated this form of pre-natal death and has found that it may occur (in animals at any rate) in the stage of the ovum or of the zygote either when the latter is a morula or a blastula (attached or unattached to the decidua). He thinks that these deaths are not due to inflammation or to microbial attacks but simply to an incapability to live and develop properly under conditions which are quite favourable to immediately adjacent zygotes; he calls it unavoidable pre-natal mortality, and estimates it at 40 per cent. in the human subject. In addition, other zygotes die from alcohol, lead, x rays, and the like, constituting the avoidable pre-natal death rate. The usual clinical expression of all such deaths will be sterility. "Pre-natal death" is not a quite suitable name, for it is too wide; "germinal" or "zygotic" would, perhaps, be better.

With regard to deaths in the embryonic period of ante-natal life—that is, after the zygote has become attached to the decidua membranes and has differentiated into embryo and embryonic appendages, the clinical expression will be abortion. It must not be forgotten, however, that abortion due to some purely passing maternal cause will also result in death of the embryo or young foetus, for the expulsion of the non-viable organism puts it in an environment which is fatal to it. No clear distinction can be drawn between deaths in the germinal and deaths in the embryonic periods of ante-natal life; thus in the well-known hydatidiform mole embryonic death may possibly occur in the blastula stage, and the further pathological changes take place later in the embryonic appendages. Among recent work on embryonic deaths and deformities, that of the late Franklin P. Mall³ stands out pre-eminently; of the late Franklin P. Mall stands out pre-eminently; the magnificent volume published by the Carnegie Institution of Washington, entitled *Studies on Abortuses*, by Mall and A. W. Meyer, is a notable addition to the literature of this difficult and yet immensely important subject. It is permissible to guess (one can hardly do more) that the causes of death in the germinal period continue to act in the embryonic, and that others come into play, such as all sorts of morbid changes in the decidua and embryonic membranes; it is certain that such deaths constitute a large part of ante-natal mortality. The subject, however, has great dimensions, and as it is rather with foetal death after viability that this discussion is concerned, no further consideration can be given to it.

The result of foetal death after the arrival of the term of viability is, according to recent but incorrect terminology,

a stillbirth, and in the great majority of cases it is accompanied by the *post-mortem* change known as maceration. If the death have occurred only a day or two before labour and birth the macerative process may be so slight as to be unrecognizable by the naked eye, but such cases are not numerous. The causes of foetal death accompanied by maceration are difficult to group; the following is a useful if not a complete or an exact classification: (1) Syphilis transmitted from the mother. (2) All other kinds of infection or disease transmitted from the mother, and showing itself in similar form in the foetus, such as small-pox, measles, scarlet fever, malaria, pneumonia, tuberculosis (very rarely), cerebro-spinal meningitis, and typhoid fever. (3) Morbid states of the foetus dissimilar from the diseases in the mother which cause them, such as the foetal changes in maternal heart disease, in eclampsia and the pre-eclamptic state, in hepatic disease, in hyperemesis, etc. (4) Morbid states of the foetus the result of poisoning of the mother with lead, mercury, alcohol, nicotine, etc., including the drugs taken with criminal intent to produce abortion or premature labour. (5) Placental morbid changes of all sorts, but particularly of an haemorrhagic kind. There must necessarily be some overlapping between this and the other groups of causes, but it must be retained as a useful means of roughly separating the causes into maternal, foetal, and placental—an old but not an exact division. The placenta is, of course, the most important organ of ante-natal life, and therefore it is, when diseased, dominant in foetal death; possibly it gives the coup *de grâce*, so to say, in all foetal deaths, whatever be the initiating cause. (6) Morbid states of the foetal annexa other than the placenta, such as adhesions of the amnion, excess of the liquor amnii, etc. (7) Foetal traumatism, including knots and twisting of the umbilical cord, separation of the placenta, etc. (8) The so-called idiopathic diseases and malformations of the foetus, including general dropsy, ichthyosis, endocarditis, cystic kidneys, and all the grave monstrosities. (9) Morbid states of the foetus of an ancestral nature, such as haemophilia, in which the mother is unaffected but has transmitted something pathological to the offspring. This is a small and dwindling group, as is also (10) the group of causes acting directly from the father through the spermatozoon.

Holland¹ has adopted another system of classification for these ante-natal stillbirths, dividing the causes into primary, such as maternal albuminuria, and consequent factors, such as the associated placental state, the direct action of the maternal poisons, etc. There are advantages in this plan but also disadvantages, and it is indeed doubtful whether our present knowledge warrants a final choice of method of grouping.

It is not to be hastily concluded that all the causes enumerated above are always or even often lethal. It must not be forgotten that the interior of the uterus is perhaps the best place in which to have a disease or a malformation. Under normal circumstances the uterine cavity is free from pathogenic microbes, and even when these infest the maternal blood the placenta may protect the foetus against them; in all conditions the foetal environment is conducive to rapid and complete recovery. Further, the life of the unborn infant is not so easily endangered as that of the child after birth; so long as the placenta is healthy the foetus may live on although its tissues are grossly diseased or its organs malformed or even absent. In ante-natal circumstances life is compatible with conditions which are immediately lethal in the post-natal environment.

When one passes to the consideration of the causes of *intra-natal* death the last-named conclusion assumes great importance. The conditions which permitted ante-natal life to continue (although of course on a low plane of vitality) become immediately lethal as soon as the birth of the child begins and are obviously fatal as soon as it has ended. For example, a foetus with general foetal dropsy² may live in the non-existent intrauterine environment, so long as the placenta remain active; but when it begins to pass through the maternal canals it may through its soft bulk be squeezed out of existence or killed by being tapped by the accoucheur or after birth it may find itself unable through the presence of fluid in its body cavities to commence pulmonary respiration. Marked monstrosities have the same effect; fused twins, for instance, may flourish *in utero*, but their passage through the pelvis may quickly prove fatal to them. To this peculiar kind of delayed lethal action I gave, long ago, the name of "potential mortality" when it proves fatal and of "potential morbidity" when it simply gives rise to symptoms. It may be compared to the state of the man with advanced heart disease

who rises from his bed and runs to catch a train, or of him who with a large aortic aneurysm allows someone to make him so angry that he "sees red."

In the first group, therefore, of the causes of *intra-natal* foetal death may be placed all the conditions (diseases and malformations) which have allowed the unborn child to survive, but which prove fatal to him during birth or immediately thereafter. In addition to those already named must be inserted pre-maturity and post-maturity. The second group will contain all the complications of labour, but especially those causing foetal asphyxia, such as separation of the placenta, placenta praevia, and prolapsed cord; those producing traumatism, such as the contracted pelvis and the large infant; and those leading to delay in birth, such as transverse and breech presentations, face cases, occipito-posterior positions, and the like. Into a third group will fall the *intra-natal* stillbirths, due directly to the methods of delivery: the cause may be, for instance, craniotomy, decapitation, or evisceration, soon to be abolished altogether one hopes; or it may be forceps extraction applied in unsuitable cases with the force of a craniotomy, or with an antero-posterior or oblique grip of the head; or it may be version done under unfavourable circumstances; or it may be the induction of a too premature labour. A fourth group of *intra-natal* causes are the infections: when labour is prolonged, especially after the rupture of the membranes, microbes may gain access to the foetus and set up disease, such as pneumonia from the pneumococcus and ophthalmia from the gonococcus; in most cases these *intra-natal* infections do not prove immediately fatal or even dangerous, but in some instances, as F. J. Browne³ has shown, they do, and they must be added to the list of occasions of *intra-natal* death. In this group of causes it will be difficult to avoid overlapping, and death may follow not from one but from several etiological factors, primary and consequent; obviously the syphilitic foetus will be less able to withstand traumatism in the act of birth than an otherwise healthy one, and will die from the disease with, say, a visceral haemorrhage added on.

Some early *neo-natal* deaths are very closely connected with stillbirths. Morbid causes not potent enough to kill the foetus *in utero* or in the act of birth may be able to do so in the hours or days which follow the beginning of post-natal life. There are now, of course, new sources of danger. The foetus is now an infant and falls under the influence of causes of death from which he was shielded *in utero*. In order to prevent ambiguity in nomenclature it will be well to adopt Eardley Holland's definition⁴ of the end of foetal life as coinciding with the commencement of pulmonary respiration; until it has breathed the foetus will remain a foetus, and post-natal life will not begin till then. The name "foetal death," therefore, will still be applicable if the *intrauterine* type of life present at birth is not transformed into the post-natal type—if, in other words, transanimation be unsuccessful. The awkwardness in nomenclature is unavoidable, for the vital statistician will be using one method of counting the beginning of life and the pathologist and obstetrician another; possibly a consultation between the two groups of persons who are interested in early *neo-natal* deaths would be productive of clarification of thought and regularization of practice and procedure.

The causes of early *neo-natal* deaths will include all these already in action in ante-natal and in *intra-natal* life; to these will fall to be added those which become effective after birth, comprising, of course, all the results of microbial infection made possible by the emergence of the foetus into the environment of post-natal life. At one time the writer thought of these new environmental causes as coming suddenly into play; but, as has been seen, this requires revision in the light of what has been discovered of the possibilities of *intra-natal* infection. To sum up, early *neo-natal* deaths may be due to (1) all the ante-natally developed conditions which without being absolutely incompatible with post-natal life yet render its continuance too difficult for it; (2) all the conditions contingent to birth which are due to traumatism or to infection then and which, while permitting the beginning of post-natal life, prevent its continuance; and (3) all the new dangerous or actually lethal conditions to which post-natal life is liable either from the stress of the new and less protecting environment or from the ignorance and folly of the persons into whose hands the new life is committed. With such a concentration and intensity of morbid causes in so new an environment there need be no surprise that the death rate of the first month is the highest recorded in the whole course of post-natal existence.

Pathology of Stillbirths and Neo-natal Deaths.

It is necessary at the very outset to state and to repeat the statement that there is no more difficult department of investigation than that of the pathology of ante-natal, intra-natal, and early post-natal death, and especially of ante-natal death. Omitting the further problems of germinal and embryonic death as outside the scope of the present communication, one is nevertheless faced by an immense field of unsolved problems. Admitting a multiplicity of little understood morbid causes, the investigator is met with the additional difficulty of the compulsion of their mode of action, a mode which must on account of peculiarities of environment and type of life be quite special and be further obscured by being carried on in the concealment of the uterine interior. It will require all the concentration of the workers under the conjoint scheme of investigation which has been set agoing so happily and wisely by the Medical Research Council to clear up not all, but simply some, of the problems of the pathology of ante-natal and early post-natal death, and this must be succeeded by specialized work along new lines to wrest the remaining secrets from "Nature's close reserve."

How, for instance, does an organism possessed of only ante-natal life die? What is the mechanism of the death of a foetus whose respiration is a tissue one and not a pulmonary? To what extent must one alter and adapt one's ordinary thinking when one is dealing with an organism in which integrity of tissue counts for little so long as the placenta remains active and healthy? How must one reconstruct one's notions of a death which is followed by *post-mortem* changes unaccompanied by putrefaction—death's usual livery, so to say? Even in respect of intra-natal and neo-natal death there must be special variations in mode of incidence and extension of pathological change. Adult or post-natal life stands upon a tripod of respiration, circulation, and innervation; but upon what does a foetal or an intra-natal life stand? Extraordinarily advanced morbid changes up to nearly complete destruction may be present in the foetal organs and yet ante-natal life continue; the foetal heart may cease in the act of birth and the newborn infant may lie without breathing for half an hour or longer, and yet in both cases post-natal life may be established and continue for seventy years. What is the pathology of, say, the oligopnoeic twilight-sleep baby?

Obviously there is a great and wide field for research here. Where must one begin? The answer is, in the first place, with the study of maceration. This peculiar non-putrefactive *post-mortem* change underlies the whole of the pathology of ante-natal death; it is the common basis of the morbid anatomy of the ante-natal stillbirth. Before one can rightly understand the pathology of the dead foetus one must have a clear mental picture both of the naked-eye and histological appearances of the macerative changes. One must construct, so to say, the common factor of maceration before one can differentiate the special changes due to individual diseases in the foetus and its placenta. The custom of saying that because the foetus was macerated there was no use in examining it microscopically or bacteriologically must be abandoned. There will be difficulty in recognizing what is merely macerative from what is distinctively the result of disease, but the difficulty is capable of being overcome. In this direction Dr. G. I. Strachan* (one of the research pathologists working under the Medical Research Council) has quite recently shown what the exploration of the common histological changes in the ante-natal environment is. It will be possible unerringly to pick out the superadded and specific changes.

The dissociation of the composite photograph, so to say, of the pathology of the dead and diseased foetus will soon be a task easy of accomplishment. With this preliminary difficulty overcome further progress will be rapid, and the histological separation of simple maceration from, say, the changes peculiar to ante-natal syphilis will be a matter of routine. Of course, bacteriology will play a large part in all such work. Then, and only then, will it be possible to form as accurate an opinion upon the cause and mechanism of ante-natal death as one does now of post-natal dissolution at the necropsy of a child or an adult. A great deal more will have been accomplished: new light will be thrown upon the pathology and morbid anatomy of the foetus in which the processes are often uncomplicated by microbial invasion to reach the basal phenomena of tissue death. Another preliminary investigation not yet completed is the discovery of

the laws regulating the transmission of microbes, toxins, toxic agents, and food substances through the placenta, to or from the foetus. Another line of investigation will be the exploration of the effect upon pathological changes in the foetus of the arrival of germs and toxins of disease and of toxic agents of all kinds by way of the umbilicus. It is difficult always to recollect that the avenue of entrance into the foetal economy is by the navel; but undoubtedly the fact is of great significance in regard to the distribution of lesions, the location of morbid processes; and the relative degree of injury done to various organs. For instance, when the typhoid organism arrives in the foetus via the umbilicus the lesions produced differ in their character, vary in their areas of maximum intensity, and attack with violence viscera hardly affected at all in child or adult, leaving others alone. Much here awaits the earnest worker. There are many other things to be done; but the writer is not offering an ordinance survey map on a generous scale of the territory of ante-natal disease and death—he is merely blazing a trail through a part of the country. As he said twenty years ago, the hinterland of ante-natal pathology is of immense extent, and it has been penetrated only by a few resolute explorers in a few directions.

Prevention of Stillbirths and Neo-natal Deaths.

The great purpose underlying all the investigation which has been outlined is the introduction of life-saving. It is true that the entrance into an undiscovered or little known country, whether that country be geographical, scientific, pathological, or histological, has the allurements of an adventure, and is a call to which the spirit of the searcher after novelty responds with alacrity; but if that were the sole incentive the advance would to me at least, and to many like-minded with myself, lack much of its true inspiration—namely, the reduction of fatalities in young life, the bringing into the world of stronger infants, and the relief of maternal suffering and disappointment. If David Livingstone had disappeared into Central Africa taking his life in his hands merely to bring back news of peoples, animals, mountains, rivers, strange, novel, or curious, his journey would indeed have been a wonderful achievement and well worthy of record in the annals of mankind. But it was to carry life that he put himself in jeopardy; it was to take remedies and cure of disease to the millions who had then not; it was to proclaim liberty to captives and death to slavery, and to open to the inward sight visions of a life with a marvellous content, with great and generous spaces, and with undreamed-of possibilities; and so he has passed into the front rank of the world's benefactors, and being dead he yet speaketh.

So, too, it is with the subject of to-day's discussion. We study stillbirths that we may prevent them; we attack death with scalpel, microscope, and culture medium; and we try to circumvent the ending of life before birth by ante-natal supervision and care. Death differs from disease in being amenable to prevention alone. So prevention of stillbirths is the one means of treatment. There will doubtless come a time when we shall be able to diagnose that a foetus is ill and in danger of death; in the meantime ante-natal diagnosis is chiefly guesswork, with the possible partial exception of syphilis, in which a positive Wassermann in the mother at least suggests a positive in the unborn infant; diagnosis, therefore, follows death, and consequently treatment must be preventive. Every expectant mother must be given preventive treatment in view of the possible death of her child *in utero*; all must be supervised to prevent the percentage incidence of stillbirths, which is indeed as yet unenumerated, but is surely known to be not small.

The general principles of the prevention of stillbirths can be clearly stated. In the first place it is necessary to watch for and treat every morbid condition of the mother which may be detected during the course of her pregnancy. If this be done with success the incidence either of these diseases in an identical form, or of their effects in a different form, upon the foetus will be prevented. There is not scope to give details, but one is thinking, of course, of syphilis, of albuminuria, and all the toxæmias, of the exanthemata, and of maternal heart, lung, and liver disease. It is not claimed that this treatment of the mother in her pregnancy will be sufficient. Prevention must begin before she is pregnant—it must go back to her childhood, and it must be directed towards her parents and even ancestors; but these are means for the future, and whilst they are important enough it is essential that the immediately possible thing be attempted first: Watchful, adequate supervision and treatment (when

needed) must therefore be given to all expectant mothers. This involves not merely the setting up of ante-natal clinics and the co-operation of all doctors who have in private practice the charge of obstetric cases, but also the provision of beds in hospitals and homes for ill expectant mothers. It means the hospitalization of the sick and pregnant in the population. This is being accomplished in a measure, but it must be general; it will mean great expense, but it has to be faced. To speak in military terminology, its chief objective will be the abolition of ante-natal death—in other words, the macerated foetus.

In the second place, it is necessary to watch for and correct every anomaly in the relation of the foetus to the mother, in the obstetric sense, before the oncoming of labour. This is for the purpose of preventing intra-natal death, and constitutes the second great purpose of the ante-natal clinic in hospitals and of ante-natal supervision in private practice. Again, it is impossible to name all the means available, but reference may be made to external version of podalic lies done in every case, but especially in the primipara; to rectification by the hands or by the useful expedient of pads in occipito-posterior positions in vertex presentations; to early recognition of contracted pelvis or of undue foetal size, and the consequent unhurried choice of the best method of delivery; and to early hospital observation of haemorrhage in the first or in the later months of pregnancy, with the elimination of the hopeless cases of placenta praevia brought into hospital after the occurrence of massive and devastating bleedings (rightly called "floodings"). There is obviously a great life-saving or stillbirth-prevention sphere in obstetric *provision*. What hospital physician does not know and dread the case of pelvic contraction sent into his wards after forceps has been applied several times unsuccessfully outside? Who does not dread the persistent occipito-posterior late in the second stage of labour? What hopeful thing can be said of the woman bled white from the external haemorrhage of a neglected placenta praevia or from the concealed haemorrhage of a premature separation of the placenta when one sees her, then for the first time? Every one of these emergencies is robbed of half its terrors if there has been ante-natal, adequate, alert supervision. And again, one is only skimming the surface of illustrative cases.

In the third place, to prevent intra-natal stillbirths a complete revision of all existing methods of delivery must be undertaken in the interest of the foetus. One must look afresh at everything. Every complication of labour (and there are not few) must as regards its management be critically reconsidered with the view of saving, if possible, both mother and infant. Here is the new law: In any case of difficult or dangerous labour, except when there is evidence that the foetus is already dead, that method of delivery should be chosen which without sensibly increasing the risk to the mother holds out a fair chance of life for the child. It might be more emphatically and uncompromisingly stated, but it will serve meanwhile. There is the case of placenta praevia: if the child be alive with a heart rate which does not suggest impending death, one ought to consider whether it is justifiable to employ the pelvic end of the infant as a plug to check the maternal bleeding at great risk to the infant and whether one ought not rather to do Caesarean section while the mother is in a condition to have it done with a comparatively small degree of danger. In every instance craniotomy on the living infant calls for the closest scrutiny. The new mental attitude to it should be: How has this obstetric disaster come about, and what ought to have been done to prevent it? What was the right thing to have done in, say, the persistent mento-posterior, the impacted occipito-posterior, the contracted pelvis, the large and possibly post-mature foetus, the locked twins, the prolapsed cord, and so on? Each case of craniotomy should be suspect.

It must be remembered that these three general principles in the prevention of stillbirths (ante-natal and intra-natal) must be applied in association in order to get the best results. They constitute what Eardley Holland's brilliant and felicitous phrase designates the strategy and the tactics of obstetric prevention; ante-natal supervision is the strategy and intelligent, far-sighted, intra-natal treatment is the tactics which together bring victory. The perfect victory is mother and a living infant who is
Some years ago I counselled the
ks on obstetrics to put in a special
chapter on ante-natal supervision; my advice now is, Let the
principles of ante-natal supervision and intra-natal tactics on

behalf, of both mother and child so penetrate the whole book that there shall be no need for a special chapter.

As an instance of the supreme importance of co-operation between the ante-natal and intra-natal methods of prevention the case of syphilis in the woman with a contracted pelvis may be mentioned. If the woman have not had one or two courses of novarsenobenzol injections her foetus will arrive in labour with blood vessels so fragile that an ordinary forceps delivery or merely a long labour will cause a stillbirth; on the other hand the foetus may by ante-natal maternal treatment have been rendered practically normal, but forceps wrongly applied in labour may finish its chances.

In the fourth place there is a general principle which applies to early neo-natal deaths and their prevention. Some of these are extraordinarily nearly allied to stillbirths; some of them are the result of the very same causes which, acting more potently, produce stillbirth. There are, for instance, the intracerebral haemorrhages. Much more is now known about these accidents in labour or results of disease in pregnancy. The bleeding at birth may be insufficient to produce death; it may, however, cause asphyxia. It is only reasonable that the obstetrician have in mind what the infant has passed through and choose his treatment in accordance, so far as can be done, therewith; it is doubtful whether Schultz's pendulum swings are ever safe, but assuredly they are not good for a baby with blood oozing into the lateral ventricles of the brain. In other words, routine must be got rid of in the management of infants born into the world after difficult labours or abnormal ante-natal lives; the attempt must be made to differentiate the causes of their delicacy or disorder, and the appropriate treatment be given to each. The same intelligent consideration should follow the newborn child into and even past his neo-natal life. In other words the babies which may have been injured in birth or weakened before it should be "followed up." They should be put in a class by themselves; perchance they should be put in a ward by themselves; and all prematurely and post-maturely born infants should be regarded as their kill and kin.

Results.

If all the principles which have been set forth above are framed on right lines, and since ante-natal work has now been established for some time in certain places, there ought to be demonstrable the results which have been claimed in advance. The proportion of stillbirths to live births ought to have fallen. This result has been obtained. It is true that the evidence has come so far in trickles rather than in full flood, but it has come. I have already published results from the prematernity ward of the Edinburgh Royal Maternity Hospital which were highly encouraging; but I am now able to show contrasts between supervised and unsupervised cases by means of the wide sweep which the ante-natal clinics have reached within the past few years, and by the fact that statistics of stillbirths (founded, however, only upon notification) can now be had. I shall deal solely with the results in Edinburgh, simply noting in passing that in other places the good effect of ante-natal supervision has been as clearly proved. In fact, it has come to be a general statement that when ante-natal supervision on anything like an adequate scale is adopted the stillbirth rate falls by 50 per cent.

The stillbirth rate for the whole of extended Edinburgh in the year 1921 was 47.8 per 1,000, there being 9,028 births and 432 stillbirths (notification returns). About 30 per cent. of all the births occurred in connexion with the Royal Maternity Hospital—namely, 1,510 in the indoor department and 1,260 in the outdoor department and at the Leith Branch. There were 104 stillbirths in the intern department and 52 in the extern. The stillbirth rates, therefore, work out at 56.3 for the whole hospital, at 68.8 for the intern cases, and at 41.2 for the extern. During the year 816 expectant mothers attended the ante-natal clinics, including 138 suffering from venereal disease. There were also a number of venereal cases which came into the venereal disease department for delivery with no previous care at all, some of them having been transferred from the main part of the hospital where their infected condition was discovered during delivery. Among the 171 venereal disease births there were 27 stillbirths, or 15.8 per 1,000. The details of the 27 stillbirths yield noteworthy results: 1 was due to a craniotomy, rendered necessary by an error in judgement as to the relation of the foetal head to the pelvis; the mother had a positive Wassermann reaction; 15 were macerated, none of the mothers having had ante-natal treatment, 10 of them with positive and 5 with negative Wassermann; 11 were not macerated

—3 mothers with positive and 8 with negative Wassermann; of the 8 negatives, 1 mother had albuminuria, 1 marked anaemia; the remaining 6 stillbirths were due to the complications of labour—5 of the mothers had no ante-natal treatment.

If, therefore, the 171 venereal disease births be divided up into those which received ante-natal treatment (138) and those which did not (33), and the stillbirths be allocated amongst them, there are found to be 7 in the former (ante-natally supervised) group and 20 in the latter (not ante-natally supervised) group, giving stillbirth rates of 50.7 per 1,000 and 606 per 1,000 respectively. This is a very striking result. The maximum stillbirth rate is reached among the venereal disease cases which had received neither ante-natal obstetric supervision nor ante-natal antivenereal treatment (606); thereafter followed in order the rate for the intern cases (68.8), for the whole hospital (56.3), for the ante-natally supervised and treated venereal disease cases (50.7), for the whole city of extended Edinburgh (47.8), and for the extern cases of the hospital (41.2). If now, and finally, one looks at the stillbirths among the supervised patients at the ante-natal clinics who afterwards were delivered in connexion with the hospital and who were free from venereal diseases, one discovers an extraordinarily low rate. There were 4 stillbirths in 678 so supervised and non-infected cases, or a rate of 5.9 per 1,000.

Stillbirth Rates for Edinburgh in 1921.

For the whole (extended) city, 432 stillbirths in 9,028 births	47.8 per 1,000.
For the whole practice of the Royal Maternity Hospital, 156 stillbirths in 2,770 births	56.3 "
For the Intern Department (104)	68.8 "
For the Extern Department (52)	41.2 "
For the Venereal Disease Department	157.8 "
Receiving ante-natal supervision and treatment (7 in 138)	50.7 "
Receiving neither ante-natal supervision nor treatment (20 in 33)	606.0 "
For the whole practice of the hospital	56.3 "
For the 678 ante-natally supervised pregnancies (excluding the venereal disease cases)	5.9 "
For the 816 ante-natally supervised pregnancies (including the venereal disease cases)	13.5 "

Thus the extremes are discovered: 606 per 1,000 among the expectant mothers suffering from the venereal diseases and with neither supervision nor antisyphilitic treatment in their pregnancies, and 5.9 per 1,000 among the women free from venereal disease and supervised and, if necessary, treated in their time of expectancy.

The third rate which is worthy of attention and scrutiny is 50.7 per 1,000 for the women suffering from venereal disease who received antisyphilitic treatment and were ante-natally supervised; this rate was actually less than that of the whole hospital, and was only 3 points above the average for the whole of the city. There is no need to add words to these figures. One sees where the danger lies, and one sees where the hope of improvement comes. One other rate should be referred to: when all the ante-natally supervised cases are considered together—that is to say, when the venereal disease cases who got ante-natal supervision and treatment are included—the stillbirth rate was 13.5. The two outstanding facts, therefore, are the evil influence of the venereal diseases, and especially of syphilis, in raising the number of stillbirths, and the good effect of ante-natal supervision and treatment even in the venereal diseases in lowering that rate.

It is necessary to remember, however, that these figures must not be regarded as quite free from fallacies. In the first place they have not been passed through the hands of a professed statistician, and they are therefore subject to correction; but whilst this scrutiny may modify them individually it will not alter the general direction in which they point. There is, for instance, some overlapping, some of the cases supervised in 1920 coming into the results of 1921, and some of those supervised in 1921 passing into the results of the present year (1922). Further, some of the cases seen at the ante-natal department were not confined in connexion with the hospital, for they had been sent from private practitioners or other institutions and returned to them for delivery; a few stillbirths may have occurred amongst them that were not reported, although the number must have been quite small. To counterbalance this, however,

there is the fact that practically all the venereal cases were dealt with in the hospital, which is the head centre in Edinburgh for pregnancy cases affected with syphilis and gonorrhoea. A second qualification which one must remember is that the ante-natally supervised and treated patients included what one may call the better class of hospital cases; they comprise the women who came to arrange about their confinements beforehand, and thus showed their interest in their own health and that of their unborn infants. They were, so to say, good material, likely to yield good results. On the other hand, they also included the pregnant cases suffering from the venereal diseases which had been detected at the Venereal Disease Department in the Royal Infirmary and sent on, material which must be counted as decidedly overweighted with morbid possibilities. On the whole, therefore, there seems no reason to doubt the general accuracy of the results which, stated briefly, are: (1) the great loss of life in the form of stillbirths and the large proportion of these due to the venereal maladies; (2) the great gain accruing from ante-natal supervision and (when necessary) treatment even in the worst group of cases, the venereals; and (3) the preventable nature of a vast number of stillbirths.

The general conclusion of the whole matter seems to be that whilst much remains to be done in the study of the causes and pathology and pathogenesis of stillbirths it is possible to go forward at once in the prevention of them by ante-natal supervision and treatment with bright hopes of substantially reducing their number. Therefore every expectant mother and her unborn infant in the country ought to be able to receive efficient and adequate ante-natal care either from her own doctor or through the maternity hospitals and homes of her native land. I put this in the form of a resolution to the Section.

II.—INTRA-NATAL DEATHS.

BY

EARDLEY HOLLAND, M.D., F.R.C.P., F.R.C.S.,

Assistant Obstetric Physician, London Hospital.

[Abstract.]

EXAMINATION of a large number of stillborn foetuses shows that a larger number have died from complications of labour than from maternal or foetal diseases. These foetuses are healthy and therefore worth saving. Classification of the causes of intra-natal death is a very difficult matter; for instance, in a case of placenta praevia the immediate cause of foetal death may be a cerebral haemorrhage due to manipulation made in attempting to control the maternal haemorrhage. A practical classification, therefore, is needed under the various primary causes—namely, maternal states, placental states, and foetal states. Evidence is to be found at *post-mortem* examination that the complications of labour account for 51 per cent. of foetal deaths. This *post-mortem* evidence consists as a rule in the presence of cerebral or visceral haemorrhages. In half the cases it is found that the tentorium cerebelli has been torn. This condition has been found in 88 per cent. of dead foetuses after normal breech delivery. The present teaching is to hurry the delivery of the after-coming head for fear of pressure on the cord. In the light of the evidence now brought forward this teaching must be revised, as actually the foetus is killed by compression of the head, brought on principally by forcible efforts being made to complete the extraction of the child. The head, therefore, should be allowed time, even so long as ten minutes if absolutely necessary.

[Dr. Eardley Holland illustrated his remarks by a lantern demonstration showing tears of the tentorium, and indicating the actual lines of stress in the falx and tentorium during extreme moulding of the head, which demonstrated the exact site where such tears must occur.]

III.—FOETAL DEATH DUE TO TOXAEMIA.

BY

A. LOUISE McILROY, M.D., D.Sc.,

Professor of Obstetrics, Royal Free Hospital School of Medicine for Women, and Director of the Gynaecological and Obstetrical Unit.

[Abstract.]

I APOLOGIZE for taking up the time of the meeting by speaking on a subject upon which I know so little. After some considerable investigation of the toxæmias of pregnancy my knowledge of this problematical condition seems to grow less, because the work has opened out such a vista of much that is unknown and perhaps also much of which is unknowable, as nature yields her mysteries very grudgingly to the seeker after knowledge.

The cause of foetal death in toxæmia is unknown, although we have gained considerable information as to the manner of death, which in most cases is due to asphyxia. We find total absorption of the foetus in early pregnancy with or without extrusion of the whole ovum. In later stages of foetal development we find anaemia, devitalized and oedematous tissues, arrested development of foetus and placenta, with the arrest of vital functions.

Pathological changes in the foetal organs are found which sometimes show the character of those in the maternal organism in cases of death from toxæmia such as eclampsia. Changes such as maceration merely show *post mortem* degeneration of the foetus. The examination of the placenta and membranes contributes much to our knowledge of retro-placental and intraplacental haemorrhages, red and white infarctions, and necrosis, together with other degenerative processes such as the formation of vesicular mole or villous cystomata. These researches point to diseased conditions which have caused foetal death, but they are the investigations of results, not causes. The only method which will bring us nearer a solution of the problem of toxæmia is that whereby the maternal metabolism is investigated—namely, by skilled examination by clinical and laboratory methods of biochemical research. We must have some definite scheme or line of research to go upon, otherwise the problem will never be nearer a solution.

We know that the trophoblastic elements pour into the maternal blood stream substances, which have been called "ferments," "hormones," "toxins," and which we might as well call "x," or "the unknown quantity." These substances are normally neutralized by antibodies in the maternal blood before elimination takes place by the excretory organs. Toxæmia may occur when there is an excessive supply of toxins, when they are unduly concentrated, or when the excretory organs are defective. A combination of all these conditions may occur. As a result the foetus suffers ill health. The foetus may just survive because it is comparatively quiescent in its water bath in the uterus, but when labour occurs and an excessive supply of toxins is poured forth it collapses and dies. It may in some cases have sufficient vitality to survive normal exit at birth, but gives in when undue stress or strain is put upon it such as occurs in operative interference with labour and delivery. It may survive all adverse conditions only to succumb at varying intervals after birth. It is born alive, but may be looked upon as "a bad life" from our knowledge of its previous ill health as read through that of its mother's symptoms. The investigation of foetal welfare and foetal mortality is one of the most important branches of preventive medicine, and is the solution of a considerable amount of the prevention of infant mortality.

I would rather have the responsibility of foetal life than that of the infant, as I know I could obtain better results provided I had the requisite knowledge of conditions. It is for a greater knowledge that I plead in this paper. I do not for a moment say the welfare of the mother should ever be sacrificed for that of the foetus, but I do urge the necessity of looking upon the foetus as an individual requiring due consideration, and that reckless interference with its life should be carefully considered or abandoned in cases of toxæmia such as persistent vomiting. The life of the foetus in the eyes of the profession should be just as grave a responsibility as that of the child after birth. This is no new teaching, but is that of the Church itself.

The study of ante-natal work has taught us on two points. First, that already a great deal has been accomplished in the prevention of intra-natal death—as, for instance, in cases of accidental haemorrhage, eclampsia, not to mention other

conditions outside the present discussion, such as contracted pelvis. The best results have occurred in this direction. Ante-natal care prevents foetal death by diminishing interference at the time of birth, and therefore ensures a healthier and more vitally resistant child. As to the second point, ante-natal care is diminishing intrauterine death of the foetus by reducing the number of abortions and premature expulsions of the foetus.

The results of this division are perhaps not quite so evident as those of the first, but in time they will prove themselves convincing. They are the most difficult problems with which we have to deal. Recurrent abortions other than those due to syphilis, habitual death of the foetus, and vesicular mole are classified as due to toxæmia; but how much nearer does that bring us to their solution? Examination of the placenta shows the results of a virulent poison which has been circulating in the maternal and foetal serum.

The main predisposing cause of toxæmia is in the intestine, and evidence of this is to be found in sepsis of the teeth, constipation, haemorrhoids, and renal deficiency, the recognition of which is of vital importance in the treatment of the condition. The patient keeps a fair balance of health until pregnancy occurs, when the whole metabolism is put out of gear. Other predisposing causes are general diseases, which have a devitalizing effect upon the foetus, and it must be remembered that the endocrinous organs play an important if unknown part in the aberrations of all metabolic functions.

True toxæmia of pregnancy is virulent in character, as shown in cases of eclampsia and *ante-partum* haemorrhage, and death of the foetus frequently occurs. Investigation of the causes of foetal death is useless unless the placenta is also examined.

It is found to be a difficult problem to make a diagnosis between toxæmia of pregnancy and previous renal insufficiency. A careful chemical analysis of the blood and urine must be carried out, and I now think it is essential to make an examination of the faeces as well. The mere presence of albumin in the urine is of little help in a diagnosis, although it is frequently associated with toxæmia and death of the foetus. The diagnosis of previous renal insufficiency is made out by the history both before pregnancy and after labour. Toxæmia as a rule clears up after the expulsion of the foetus.

Examination of the urine gives the amount of excretion alone; it must therefore be made in conjunction with the blood, which shows the degree of retention. The faeces show the presence of bacteria, a very important point in itself. It must be remembered that in some of the worst cases of eclampsia the urine gives no danger signals, and many cases of toxæmia, cardiac disease, chorea, etc., produce healthy children. As for the chemical tests for urine in toxæmia, there the confusion begins. Globulin is said to be an evidence of toxæmia (Mackenzie Wallis); albumin is associated with foetal death and sometimes disappears when the foetus dies *in utero*; albumin is found in *ante-partum* haemorrhage (42 per cent., Gordon Ley); urea is diminished in amount in destructive renal conditions (normal, 2.2 per cent.); it is diminished in eclampsia and persistent vomiting of pregnancy. The estimation of urea is best carried out by the urea concentration test. Diastase, according to Mackenzie Wallis, is high in toxæmia and low in renal disorders, but in my experience this has not proved a very stable occurrence. Opinions differ and oscillate at intervals as to the value of the ammonia excretion. The presence of diacetic acid is looked upon as a danger signal. It is possible that much information will be gained from the presence of indican, indol, and other derivatives.

In the blood examination, if the urea is high (normal, 0.02 to 0.05 per cent.) it is a sign of a serious condition, and if the foetus is viable the question of induction of labour may have to be considered. Toxæmia resulting in placental separation from necrosis or haemorrhage frequently causes asphyxia and therefore death of the foetus *in utero*.¹

A differential diagnosis of toxæmia and renal disease may be of value in the prognosis of a case. On general lines toxæmia occurs more frequently in primiparae; there is oedema of the lower limbs; serum globulin is present in the urine, and the diastase is high (unchanged in blood); acidosis more frequently occurs. In renal disease symptoms occur more frequently in multiparae; there is oedema of the face

¹For a scheme of investigation and general treatment see my paper in the BRITISH MEDICAL JOURNAL, March 4th, 1922, and communication on July 22nd, 1922.

and arms; serum albumin is present; diastase is low but high in the blood; albuminuric rotinitis occurs sometimes, rarely found in toxæmia.

One may, however, go on for a considerable time discussing the various tests in use for the diagnosis of toxæmia and yet bring the subject very little nearer a practical solution. Something must be done to prevent enormous waste of foetal life, and it is of little use working under such isolated conditions as we are all doing at present. I would suggest the formation of a central committee under the control of the Ministry of Health and the Medical Research Council to discuss and carry out a scheme of investigation upon foetal welfare and mortality.

This committee should be composed of representatives of the British obstetrical societies, medical officers of health who are responsible for the work of midwives, specialists in diseases of infants, together with physiologists and pathologists—the latter including biochemists and bacteriologists. By such a committee a plan could be laid down for an organized investigation or research, and facilities could be given for work and financial aid. The notification of abortion is almost compulsory if we are going to acquire any information as to the enormous waste of foetal life.

The outcome of such research upon ante-natal conditions would not only result in a greater attention to foetal welfare, but would give results which would most clearly show the value of such preventive work in reducing the number of foetal deaths.

IV.—NEO-NATAL DEATH.

BY

FRANCIS J. BROWNE, M.D. ABERD., F.R.C.S. EDIN.*

Research Pathologist, Edinburgh Royal Maternity Hospital.

OUT of a series of 400 cases of stillbirth and neo-natal death which I have fully examined and classified there have been 153 cases of neo-natal death. The causes of death in these cases may be classified as follows:

- A. *Traumatic*: Intra-natal-hæmorrhage, other injuries, injury during artificial respiration.
- B. *Infective*: Ante-natal—syphilis; Intra-natal—pneumonia, other intra-natal infections; Post-natal—pneumonia, other infections.
- C. *Toxæmic*: Necrosis of liver.
- D. *Developmental* (congenital abnormalities).
- E. *Prematurity* (per se).
- F. *Other conditions not peculiar to the newly born*—for example, volvulus, strangulated hernia, gastro-enteritis, intussusception, etc.
- G. *Undetermined*.

I have time only to discuss very briefly some of the more important of the various causes classified in this table.

A. TRAUMATIC.

1. Cerebral Hæmorrhage.

Of this I have met, amongst neo-natal deaths, with 53 cases. In 36 of these the hæmorrhage was intraventricular—that is, into one or other or both lateral ventricles, or into the third or fourth ventricle. A study of all the cases of cerebral hæmorrhage, including stillbirths, showed that amongst full-time infants with vertex presentation hæmorrhage was practically confined to cases of difficult forceps delivery; indeed, I have only met with one case of cerebral hæmorrhage in a full-time infant in which delivery was a natural vertex. In that case the child was post-mature, and labour, though natural, was prolonged and difficult. Further, if we take 3 per cent. as the normal frequency of breech delivery it is found that the latter is ten times as likely to give rise to cerebral hæmorrhage as is delivery by the vertex.

One of the most striking points was the frequency of hæmorrhage amongst premature infants, even when delivery had been easy and natural. During the last six months in the Edinburgh Royal Maternity Hospital one birth in every 13 was premature. Assuming this to be the normal frequency of premature labours in hospital practice, it is found that cerebral hæmorrhage is ten times as likely to occur in premature labours as in labours at full time. This is a remarkable result when we consider the frequent difficulty of labours at term and the ease with which it takes place when the child is premature. The explanation is doubtless to be found in the great delicacy of the vessels in the premature foetus and the mobility of the bones of the cranial vault. The liability to cerebral hæmorrhage in premature infants was

found to be greatest at seven and a half months, less at eight months, while at eight and a half months the liability appeared to be no greater than at full time. I use the word "months" here advisedly because in a general way it is probably as accurate as if we attempted to estimate the duration of pregnancy in weeks or days from the usual data.

Intraventricular hæmorrhage is, in my experience, practically never met with except in premature infants. It was about ten times as likely to occur in breech as in vertex deliveries. The duration of life in these cases varied from half an hour to sixteen days, and it is not uncommon for an infant to live for forty-eight hours with both lateral ventricles distended with blood clot. The case which lived for sixteen days was a seven and a half months infant in which a large clot distended the left lateral ventricle. It is unusual for the infant in these cases of intraventricular hæmorrhage to show any signs which might localize the site of the hæmorrhage. It is usually blue, cries weakly, feeds badly, and, if it lives sufficiently long, gradually wastes away.

Operability.—It was remarkable that in none of my cases of cerebral hæmorrhage, except in one seven and a half months infant which lived three days, could operation have been undertaken with any hope of permanent success. In all the others failure must have resulted, partly because although in some cases part of the clot could have been removed it was associated with hæmorrhage in other inaccessible parts of the brain, such as in the ventricles, over the corpus callosum, or over the base, or with hæmorrhage in other organs like the suprarenal or lung, which in itself would probably have proved fatal. Besides, so many of these infants, the victims of cerebral hæmorrhage, become infected with pneumonia, which almost always terminates fatally in a day or two.

The chief points to be kept in mind in the prevention of cerebral hæmorrhage are, then, as follows: (1) Avoidance of breech delivery by carrying out cephalic version, whenever possible, before the onset of labour and preferably at about eight to eight and a half months. (2) Avoidance of difficult forceps deliveries. This is only possible by the adequate ante-natal supervision of every case. (3) By limiting the induction of premature labour to cases which have reached the thirty-fifth week of pregnancy; by avoiding the use of forceps on the premature child, preserving the membranes unruptured as long as possible, and manual dilatation of the cervix and vagina in front of the advancing head. The same object may be achieved by the use of hydrostatic dilators.

2. Suprarenal Hæmorrhage.

Altogether I have met with 27 cases of suprarenal hæmorrhage, but in only 6 of these was the child born alive. In several cases of suprarenal hæmorrhage the child is usually dead or stillborn, sometimes in a condition of white asphyxia, and fails to respond to restorative measures. The medulla of one or both capsules in such cases is found to be distended with blood clot. Only very occasionally has the hæmorrhage burst into the peritoneal cavity, and the cause of death is not the amount of blood lost but the shock caused by the involvement of the sympathetic nervous structures of the medulla. When the infant survives birth it usually only does so for a few hours, but I have met with one case which lived for four days. There was a massive hæmorrhage in the cortex and medulla of the right suprarenal, associated with hæmorrhage into the cortex and pyramids of both kidneys, practically destroying the parenchyma in the hæmorrhagic areas. The child was born at full time by the breech, internal podalic version having been performed on account of lateral placenta prævia.

Suprarenal hæmorrhage is almost entirely found in cases of difficult forceps and of breech delivery; it was found to be twenty-two times as likely to be associated with breech delivery as with delivery by the vertex. As regards maturity, it was found to be about three times as likely to occur in premature labours as in labours at term.

3. Other Injuries.

Amongst these are comprised such conditions as sub-capsular hæmorrhages in the liver, some of which may burst into the peritoneal cavity, massive hæmorrhages in the lungs, and hæmorrhage in the kidneys. A few cases of craniotomy in which the infant breathed after birth must be included in a classification of the causes of neo-natal death, but the distinction from craniotomy as a cause of intra-natal death is merely of academic interest and has no practical importance.

* Working under the Medical Research Council.

B. INFECTION AS A CAUSE OF POST-NATAL DEATH.

We now come to the next large group of causes of post-natal death—namely, the infective causes, which may be conveniently divided into ante-natal, intra-natal, and post-natal, according to the time when the infection occurs.

Syphilis.

Under ante-natal causes the most important is syphilis. Altogether I have examined 35 cases in which the cause of neo-natal death was put down as syphilis. With the exception of one infant which lived for six weeks, all died within two weeks after birth, and in a few cases the infant only gasped once or twice. What are the points that will assist us in making a diagnosis of syphilis in these cases?

1. *A History or Clinical Evidence of Syphilis in the Mother.*—Such a history is in reality rather infrequently found. Thus, out of 17 macerated syphilitic foetuses in whom the maternal history could be fully obtained, in 13 cases there was no maternal history or clinical evidence of syphilis. It is, however, significant that all those who gave evidence of syphilis were, with one exception, primiparae, whilst all the others were multiparae, and were with two exceptions, judging from the obstetrical history, cases of old-standing infection. I think it is likely that in such cases the past evidences of secondary syphilis had been overlooked by the mother on account of the lapse of years.

2. *A Bad Obstetrical History in the Mother.*—In a multipara there is generally, unless where the infection has been a recent one, a history of stillbirth, abortions, or neo-natal death. I have noticed that the sequence of events is frequently rather different from the textbook picture, which is that the first pregnancies after infection end in abortions or in the birth of macerated foetuses, while in later pregnancies the child may be born prematurely with lesions of syphilis and soon die. Still later it may remain apparently healthy for years. More frequently in my experience there is a succession of macerated foetuses, or a macerated foetus may be succeeded by a child which lives for a few weeks, months, or years, only to be followed again by a macerated foetus or an abortion. Such an apparently indiscriminate mixture might be explained by a fresh infection, but I have never found anything in the clinical history to suggest that, and the matter is one more added to the many difficult problems of latent syphilis.

3. *A Positive Wassermann Reaction in the Mother.*—A positive Wassermann reaction is very often absent in old cases of maternal syphilis. On the other hand, one not infrequently finds a strongly positive blood Wassermann in the mother, where the child shows no evidence of syphilis either naked-eye or microscopic. The test is therefore at best merely an aid to diagnosis.

4. *Presence of Syphilitic Changes in the Placenta.*—The weight ratio of the normal placenta varies from 4 to 13. In my syphilitic cases I have found that the placenta was definitely enlarged in 50 per cent., so that its weight ratio exceeded 4. Even when there is not this definite increase of weight ratio the syphilitic placenta may often be recognized by its pallor and by its unusual thickness. Greater assistance is usually obtained, however, by the microscopical examination, which shows the villi to be enlarged and non-vascular, with a consequent diminution of the intervillous space. The enlargement of the individual villi explains the enlargement of the placenta as a whole. When we consider that the weight ratio of the normal placenta varies from 4 to 13 we see why it may be said that the syphilitic placenta is always enlarged—that is, it is enlarged for that particular placenta, which, had it been normal, would have had a low weight ratio. While it is true that microscopical examination of the placenta is of the greatest assistance, yet border-line cases are not infrequently met with in which a dogmatic pronouncement is impossible.

5. *Signs in the Child itself.*—The child is usually premature and badly nourished, and it may show clinical evidence of syphilis in the form of skin eruptions.

(a) *Presence of Spirochaetes in the Foetal Organs.*—This is the only absolute sign of syphilis. While in the macerated syphilitic foetus I have found them present in 70 per cent. of cases, in the fresh syphilitic I have only found them present in 4 out of 32 cases, or 12.5 per cent. One of those syphilis in which I failed to find spirochaetes was the twin of a macerated foetus, in whose organs they were especially numerous.

(b) *Enlargement of the Liver.*—It seems to be an almost universal belief that liver enlargement is constantly present

in syphilis of the newly born. I am quite sure that this is by no means so. Thus of 100 full-time fresh normal foetuses in which syphilis was carefully excluded the mean ratio of the liver was 21.1, but amongst these was a liver with a weight ratio of 13.3, one of 14, one of 14.4, etc. Of 14 full-time fresh syphilitic foetuses I found the mean ratio to be 19.9, amongst which there were only 2 with a weight ratio heavier than 13.3, which was the heaviest weight ratio amongst the full-time healthy foetuses. The weight ratios of these 2 were respectively 12 and 13. Amongst 14 eight to eight and a half months syphilitic foetuses only one had a weight ratio (12.5) heavier than the heaviest normal (14).

Amongst seven to seven and a half months' infants a heavier weight ratio was actually found in the case of one which was normal (12.5) than in any of the syphilitics at this period, the heaviest weight ratio amongst which was 13. It is true that the mean ratio of a large series of syphilitic livers is heavier than that of a large series of healthy livers, but in dealing with an individual case averages do not help. What does help is to know whether that particular liver is abnormally large, and it is only abnormally large if it is heavier than the heaviest normal. Of 35 syphilitic infants born alive I have only met with an abnormally heavy liver in 5, or 14 per cent. It is interesting to note that Holland^{*} has arrived at a somewhat similar conclusion; he says, "Enlargement of the liver is worthless as a diagnostic sign of syphilis if taken by itself, for it is so often found in definitely non-syphilitic foetuses."

(c) *Enlargement of the Spleen.*—This I have found a more helpful and reliable test. Thus, out of the 35 fresh syphilis it was found that in 12, or 35 per cent., the weight ratio of the spleen was increased so as to be greater than that of any normal spleen that I have met with.

The heaviest weight ratio in a series of 100 full-time healthy spleens was 177, while of 42 cases at eight to eight and a half months it was 155. The latter was the heaviest weight ratio I have ever found in a healthy spleen. Therefore a weight ratio definitely higher than this should be looked upon as an abnormal enlargement, and as strong evidence in favour of syphilis. The edges of the syphilitic spleen are usually rounded; on section the Malpighian bodies are poorly marked, and microscopically the enlargement is found to be almost entirely due to a hyperplasia, with, as a rule, no definite increase in the reticulum or plasma cells.

(d) *Chondro-epiphysitis.*—While in the macerated foetus chondro-epiphysitis was present in the majority of cases of syphilis, in the fresh syphilitic I have found its presence comparatively infrequent. Thus, out of my last 11 cases I found it absent in 6, indefinite in 3, and definitely present in 2. Increased experience has served to confirm me in my conviction that if absence of chondro-epiphysitis be relied upon as evidence of the absence of syphilis, then a large proportion of syphilis will be overlooked.

This concludes the evidence of syphilis usually found by naked-eye examination. I have only once or twice met with pneumonia alba sufficiently well marked to cause changes visible to the naked eye. The thyroid and pancreas may be firmer and paler than normal if they are the seat of interstitial change, but the alteration in appearance and consistency is never definite enough to be of assistance in diagnosis.

It is thus apparent that one may review the maternal history, examine the placenta, and carry out a careful *post-mortem* examination and still be left in doubt as to the presence of syphilis. In such cases the greatest assistance is obtained from histological examination of the organs; especially of the thyroid, thymus, lungs, liver, and pancreas, in some or all of which changes of the greatest importance may be found, and which are briefly as follows:

Thyroid.—Increase of the interacinar connective tissue, which presses upon and destroys the acini more or less completely. There is absence of colloid and proliferation of the cells lining the acini into the lumen.

Thymus.—If the child is marasmic the thymus is atrophied and weighs as little as 2 or 3 grams instead of the usual 8 or 10 grams. The cortex of the lobule has disappeared and only the medulla remains; lymphocytes are exceedingly few, and this accounts for absence of the thymus juice on squeezing the cut surface. There is marked increase of the connective tissue in the lobules and the interlobular septa are much thickened. In addition there is a peculiar change in the corpuscles of Hassall, which are enlarged; and their contents

* Report on the Causation of Foetal Death. Ministry of Health Reports, 1922, p. 33.

T

In figures based on admissions to a maternity hospital, where the proportion of cases of delayed and complicated labour is enormously greater than the proportion of abnormal labours in the population generally, the incidence of stillbirth must be much too high, and in estimating the actual incidence of abortion from the records of such cases a similar difficulty arises. Making allowance for certain modifying factors, it will be admitted that statistics drawn from hospital admissions without selection of cases, while of little use as an indication of the actual incidence of abortion and stillbirth, are of value in estimating the relative incidence of abortion or stillbirth in syphilitic and non-syphilitic women of the "hospital class."

The results of the present study with regard to syphilis in the mother as a factor in the etiology of abortion, premature birth, and stillbirth are as follows:

1. *Abortion* (that is, pregnancy ending before the seventh lunar month).—There were 12.8 per cent. of abortions in a series of 1,000 pregnancies. In the group of cases in which the mother's Wassermann reaction was positive the incidence of abortion was 6.17 per cent., and in the group of cases in which the mother's Wassermann reaction was negative the incidence of abortion was 13.17 per cent. While there is thus, apparently, an incidence of abortion in the positive group equal to about half the incidence in the negative group, one cannot lay great stress on the point, for the number of positive cases in which abortion occurred forms too small a series for numerical comparison. The conclusion seems justified, however, that there was no greater incidence of abortion in the positive group than in the negative group.

2. *Stillbirth*.—In the 737 cases in the series in which a viable foetus was delivered the percentage of stillbirths was 16.46. The incidence of stillbirth in the positive group was 18.07 per cent., while in the negative group it was 15.15 per cent. From these figures it is seen that stillbirth occurred in the series with slightly greater frequency amongst syphilitic than amongst non-syphilitic women; and this, it is to be noted, was in a collection of cases containing an unusually high proportion of abnormal labours.

3. *Abortion and Stillbirth*.—Considering these two conditions as one group, it is seen that in the present series of cases abortion and stillbirth occurred with almost equal frequency in syphilitic and in non-syphilitic women. The greater incidence of abortion in the negative group as compared with the positive group has already been noted, but for the reasons given one cannot draw any more definite conclusion on this point than that abortion was not more frequent amongst syphilitic than amongst non-syphilitic women in the series.

The greater incidence of stillbirth in the positive group as compared with the negative group is remarkable, particularly when it is remembered how many of the cases showed obstetrical complications. Even without making allowance for this, and still more so if such allowance be made, it is clear that in the present series of cases stillbirth was distinctly more common in syphilitic than in non-syphilitic women.

4. *Premature Birth*.—The incidence of premature birth amongst the viable infants of mothers with a negative Wassermann reaction was 19.88 per cent., while the incidence of premature birth amongst the viable infants of mothers with a positive Wassermann reaction was as high as 32.54 per cent. These figures, based on the 737 cases of the series in which a viable infant was born, illustrate in a remarkable way the importance of syphilis as a cause of premature birth. The point is, however, emphasized by the fact that, of the 133 premature children born to mothers with a negative Wassermann reaction, 34.61 per cent. were stillborn, while of the 27 premature children born to mothers with a positive Wassermann reaction 68.75 per cent. were stillborn.

5. *Relation between Abortion, Premature Birth, and the Presence of Syphilis in the Mother*.—By taking the three conditions together—abortion, premature birth, and stillbirth—one is able to realize what I take to be the true significance of their relation to syphilis in the mother. It has been pointed out above, with reference to the present series of cases, that if abortion and stillbirth are grouped together the incidence of the combined group shows little difference in syphilitic as compared with non-syphilitic mothers (22.58 per cent. and 24.94 per cent. respectively). The incidence of stillbirth, taken by itself, has been shown to be somewhat greater in the syphilitic than in the non-syphilitic group in this series (18.07 per cent. and 15.15 per cent. respectively).

It is the analysis of the figures with regard to premature birth, however, which reveals the most important effect of

syphilis in the production of ante-natal and neo-natal death. As has been noted above, 19.88 per cent. of the viable infants born to non-syphilitic mothers were premature, while of the viable infants of syphilitic mothers 32.54 per cent. were born prematurely. Of these premature infants 34.51 per cent. were stillborn in the non-syphilitic group and 68.75 per cent. were stillborn in the syphilitic group. It is, then, as a cause of premature birth and stillbirth that syphilis is of greatest importance in the later months of pregnancy.

Summary and Conclusions.

From a study based upon the Wassermann reaction of over 3,500 specimens of blood and upon the clinical records of 1,000 pregnant women it is concluded:

1. That between 9 and 10 per cent. of women of the "hospital class" in Glasgow show evidence of syphilitic infection.

2. That the results of the Wassermann reaction in the blood of the newborn are of little value in proving the presence of congenital syphilis.

3. That the incidence rate of congenital syphilis has been greatly exaggerated by most recent writers.

4. That syphilis in the mother cannot be shown to be a factor of predominating importance in the etiology of the interruptions of pregnancy in the earlier months.

5. That syphilis is one of the most important causes of stillbirth and of interruption of pregnancy in its later months, leading to premature birth, and, more particularly, to premature birth with death of the foetus.

VI.—PLACENTAL CHANGES IN RELATION TO FOETAL DEATH.

BY

GILBERT I. STRACHAN, M.D., M.R.C.P., F.R.C.S. Eng. and Edin.,
Assistant to the Professor of Obstetrics and Gynaecology, Welsh
National School of Medicine.

In the course of examination of any large number of still-born foetuses in order to ascertain the cause of death the condition of the placenta will in many cases be found of the utmost importance; indeed in a large proportion of cases but for a thorough examination of this organ the cause of death could not be discovered. In his recent monograph on the subject of foetal death Eardley Holland states: "No *post-mortem* examination of a foetus can be regarded as complete unless accompanied by the examination of the placenta and cord," and any worker in this line of research will surely agree with this dictum.

In cases of stillbirth associated with such conditions as, for instance, dystocia, placental changes of note are mostly absent; it is mainly in cases of syphilis, clampsia, albuminuria, or death from unknown cause that placental changes will be found.

Such changes may usefully be classified under the following two headings:

1. *The Syphilitic Placenta.*

This is in some cases quite normal in appearance; this was the case in 3 out of 8 of our series. These 3 placentas were of normal size both absolutely and relatively to the foetus; the appearance and consistency were as seen in healthy specimens, and but for other clinical factors present there was nothing to indicate the presence of syphilis in the mother. The other 5 syphilitic placentas were, however, large, soft, pale, and flabby, but no infarctions or haemorrhages were present. In these 5 cases an increase in thickness up to two inches was also present. It is to be emphasized that the three organs showing no naked-eye changes accompanied full-time foetuses, while in the other 5 cases the foetuses were premature—mostly about the thirtieth week.

Microscopically, in a well-marked case, the individual villi will be seen to be larger than normal and more closely packed, so that the field is thickly occupied by them; the stroma of the villi is thick and vessels are either absent or small and inconspicuous. Positive endarteritis was not often found and the appearance presented by the villi may be ascribed to a perivascular fibrosis which, in time, obliterates the vessels by pressure. While, in such specimens as appear normal to the naked eye, these microscopical changes are not well marked and, indeed, may at first sight appear to be absent, yet, if sections be taken from several different areas some degree (it may be slight) of these changes will be observed.

It would appear, then, that in cases where this overgrowth of the villi occurs early—presumably in the more severely infected cases—the degree of vascular obliteration will be such as to interfere with foetal nutrition and bring about premature death *in utero*, while in cases where this does not occur until later—in the less severely infected cases—the foetus may go on to full time and be stillborn or be born alive and die soon after birth when the placental interchango is cut off and the syphilitic poison confined to the body of the foetus.

2. Placental Infarctions.

Time will not permit a full discussion of this subject and the conclusions arrived at will require to be shortly stated.

In the series of stillbirths examined 46 placentae showed varying degrees of red or white infarctions; of these signs of old or recent, slight or severe utero-placental haemorrhage were present in 21 cases, or 45.5 per cent., while there was associated albuminuria in 25 cases (56.5 per cent.). The changes, both macroscopic and microscopic, in infarction formation have been worked out by several observers, notably by Eden, Whitridge Williams, and Young, and two main views are held as to their formation.

(a) Eden and Williams hold that the process consists of an ischaemia of a certain area of the placenta, consequent on endarteritis of the branches of the umbilical vessels, with their subsequent obliteration. This is followed by coagulation necrosis at the syncytial edge, which is accompanied by fibrin deposition, which fixes the involved villi together. The infarct finally consists of a number of more or less degenerate villi welded together by a mass of fibrin. This process forms one of the changes preparatory to the separation of the placenta. Infarction formation, according to this view, then, is a normal process, and constitutes a sign of seculity in a short-lived organ. But it is not explained why such changes occur only in patches; also the factors which focus the process on any particular part or parts of a placenta have, so far as is known, not been investigated. Such a process as described undoubtedly does occur, but the resulting infarcts are small and white from the outset, and, so far as could be judged, have been excluded from our present consideration.

(b) Young's view is that as the result of utero-placental haemorrhage an acute vascular injury is inflicted on that portion of the placenta related to the haemorrhage. This produces passive congestion, accompanied by dilatation of the vessels in that part, and this may be so extreme that rupture of the capillaries may occur, causing an intraplacental bleeding, which may again be localized, or to a greater or less degree infiltrating.

Such a coagulum later on shows an encircling white capsule or line of demarcation which increases in thickness until only a small central clot or later only a brown stain is left in this whitish, laminated area; and finally that also disappears, the haemorrhage now having become entirely replaced by a whitish, hard area which is, in effect, a fibrinous scar at the site of the original haemorrhage.

Such infarcts are white only in the later stages, are larger than those previously described, and are often accompanied by signs of retroplacental clot; further, while those in the previous class do not appear before the twenty-eighth week of gestation, the variety now under consideration may be found well developed much earlier. Stillbirth is brought about in these cases by the ablation of an area of the placenta sufficiently extensive to interfere with foetal nourishment. If we accept Young's views regarding the absorption of toxic products from such devitalized areas into the maternal circulation to set up albuminuria or eclampsia, it is equally feasible that a similar absorption will occur into the foetal circulation and produce toxic death there.

From these considerations it may be inferred that, should the uterus empty its contents immediately after the occurrence of such utero-placental haemorrhage, the foetus will not be macerated and the placental changes will not, as yet, have had time to develop, so that this organ, in such cases, may appear to the naked eye practically normal although microscopic examination will reveal the presence of vascular dilatation; while, if the uterine contents are retained for a time, maceration of the foetus will have occurred and placental infarctions will have developed before expulsion. Experience has confirmed these expectations, and in this class of case a macerated foetus is usually accompanied by an extensively infarcted placenta.

Relative insufficiency of the placenta requires little more than mention; it is a rare condition, having been met with by us only once in 150 cases examined. In this case the foetus was expelled at thirty-two weeks without obvious cause, being normal in appearance and structure, but the placenta was very small, weighing only 6 oz. (169 grams). Its microscopic structure was normal. The condition is brought about by an overatrophy of the chorionic villi, so that at a certain time sufficient nourishment cannot be absorbed to supply the foetus, which then dies and is expelled.

From these observations it will be gathered that placental lesions constitute an important variety of the conditions causative of or associated with stillbirth; at the risk of too great reiteration it has to be repeated that examination of the placenta of every case is very necessary in all stillbirth investigations.

DISCUSSION.

Dr. T. W. ENEN (London) said that he felt completely overwhelmed by the mass of facts which had been presented to them by the various speakers; and he would need time to digest them; but one thing was quite certain, and that was that their midwifery practice wanted improving. That meant improved teaching, and this was more a question of organization rather than anything else. Improvement was called for (1) in the conduct of labour itself and (2) in the supervision of the pregnant woman. They had heard a good deal lately of the similarity of labour to a surgical operation. If that meant that the strictest possible asepsis should be preserved that was correct, but it was a dangerous fallacy to look upon labour as an opportunity for the exhibition of manual dexterity and skill. With regard to ante-natal clinics, he could not imagine anyone more unfitted for their management than the medical officers of health. As a rule they were the least qualified for this work; unless supervision was not only conscientious but well informed, such clinics were useless.

Dr. LAPHORN SMITH (London) expressed his pleasure at hearing the papers read that morning. As regards toxæmia his experience of 2,500 confinements was as follows: (a) Toxæmias up to the seventh month were entirely preventable if seen early. (b) If not seen till after the seventh month prompt treatment of the mother was necessary, and if convulsions came on removal of the foetus as quickly as possible by the means least injurious to the mother, generally by Caesarean section. (c) The accepted teaching should be changed that version was a good procedure for delivery in difficult labour. He thought that version was very dangerous for the child—this was well known. He agreed with previous speakers that the danger did not come from pressure on the cord so often as it did from rupture of veins and membranes by the force of traction on the aftercoming head. (d) The foetus was liable to all the diseases to which the mother was liable. (e) If every practitioner were to teach his prospective cases of confinement that they must be under supervision during the whole of their pregnancy; if he made it his business to cure constipation and other causes of absorption of toxins from the digestive tract, and if he taught the women to drink more water and eat less meat there would be very few cases of uraemic convulsions which cause so many pre-natal deaths and quite a few post-natal deaths. (f) Craniotomy should disappear from practical obstetrics.

Dr. RUSSELL ANDREWS (London) agreed that ante-natal beds in hospital were absolutely essential, but he thought they would be extremely difficult to get. When obtained they must be kept for this purpose strictly. The suggestion that a Commission should be appointed was extremely important. Referring to the matter of breech delivery, he thought it was essential to obtain full dilatation of the cervix before attempting delivery. Stillbirth was much more likely where the head was delayed high up by a not fully dilated cervix than in cases where delay was caused by the perineum.

Dr. ANDERSON (Glasgow) put forward the view of the general practitioner. He would take to heart the advice given about delivery of the aftercoming head. He was greatly interested in the question of the toxæmias, as it would appear that a very large number of cases had occurred of recent months in Glasgow, possibly connected with the epidemic of influenza. He wished for advice from the leaders of the profession as patients continued to show the greatest possible

reluctance to any form of *ante-partum* examination. When it was urged by the doctor they were very apt to accuse him of going out of his way to gain fees. On account of this prejudice it was a very difficult matter for the general practitioner to carry out these recommendations.

Professor MUNRO KERR (Glasgow) agreed with previous speakers that deaths during parturition represented from 55 to 60 per cent. of all foetal deaths. Referring to the delivery of the after-coming head in cases of breech presentation he said that the trouble could be absolutely avoided by version in the later weeks of pregnancy, cranial presentation being thus secured. He thought the application of forceps to the after-coming head was extremely valuable (1) because traction was made directly on the head, (2) a better flexion of the head could be secured, and (3) extraction could be made much more slowly owing to the admittance of air which took place when the instruments were applied.

Professor R. C. JOHNSTONE (Belfast) thought that Schulze's method of artificial respiration was responsible for many foetal deaths.

Dr. STEWART (Glasgow), speaking as a worker in an ante-natal clinic, asked for a much closer co-operation between the leaders of the profession and their humbler colleagues. She was of opinion that it was extremely difficult to get patients to come for examination, but they lured them to the ante-natal clinics by sociological methods. She thought that for a generation or two women would not go to their doctors until they were actually ill. Their great difficulty in the ante-natal clinics was to get proper support; she feared that in some towns, at any rate, these clinics were not appreciated.

The PRESIDENT, continuing the discussion, said that it was generally conceded that the general practitioner was the person most responsible for unnecessary interference in labour—but was the consultant entirely without blame? Consultants were usually called in to do something to finish matters; they were expected to do something, and were not so much treating the case as helping the whole household to get it over—everyone was anxious for labour to be completed. Consultants must realize that they had to bear their share of the responsibility. The only remedy was to make the public appreciate that interference was, more often than not, for the good of neither mother nor child. In regard to version in breech cases he thought a reservation must be made, as at times delivery by the breech was best for both mother and child. In regard to the relation of the medical officers of health to the ante-natal clinics, in centres other than teaching centres, he was of opinion that they were the proper persons to administer them; they had the organization. He would be sorry for any strictures on medical officers of health to go out as the considered opinion of that meeting. Everything tending to encourage the advancement of our knowledge of ante-natal work should be encouraged.

Dr. BALLANTYNE, in closing the discussion, referred to the great pleasure it gave him to be in an atmosphere where the subject was sympathetically received. It was no longer to be regarded as a *fad*, a wild dream of infancy. As regards the position of the medical officer of health, he described how he had been consulted at every stage in working out the scheme in Edinburgh, and he thought that it was essential for them to keep in touch with the medical officers of health as a connecting link. He remarked that version in breech cases was not always easily performed even under anaesthesia, and suggested that sometimes the employment of pads and a tight binder might prove useful.

Resolution by the Section.

At the conclusion of the discussion on ante-natal and neonatal deaths the following resolution was passed:

"The Section of Obstetrics and Gynaecology (1922) of the British Medical Association is of opinion that every expectant mother and her unborn infant should receive efficient and adequate ante-natal supervision and (if needed) treatment, either from doctors in practice or in maternity hospitals and homes; and, with this end in view, recommends the Council to set up a provisional committee, consisting of representatives of the obstetrical societies and of the health authorities of Great Britain and Ireland, to confer as to the formation of a scheme for securing foetal welfare and preventing foetal mortality."

TREATMENT OF INFANTILE PARALYSIS IN CHILDREN.

BY

G. R. GIRDLESTONE, M.B., B.Ch., F.R.C.S.,

HONORARY ORTHOPAEDIC SURGEON, WINGFIELD HOSPITAL, READINGTON,
AND RHODPSHIRE; ORTHOPAEDIC HOSPITAL; HONORARY ASSISTANT
ORTHOPAEDIC SURGEON, RADCLIFFE INFIRMARY, OXFORD.

The President of the Section for the Study of Disease in Children, Sir Robert Jones, recently delivered to it an address on the treatment of paralysis in children, and it occurred to me that a practical demonstration of the methods by which the principles he described are carried out in the Wingfield Hospital, Oxford, and its surrounding clinics would be a useful addendum to his remarks.

I think that the subject is one of great clinical interest, but there is one side of it to which I would like to draw special attention—that is, the political economy of the treatment of these paralytic cases. The Education Act of 1918 has added greatly to the responsibilities of local authorities with regard to crippled children, and at the same time special attention is being devoted to these cases by surgeons in many parts of the country. The education authorities are helping to finance the treatment of these cases, and it is probable that they will look closely into the expenses to which they are thus committed, in relation to the results which are finally obtained.

We have to prove the economy and efficiency of our treatment. While it is vital that the principles of treatment shall be carried into effect, we should aim at using simple appliances, for simplicity means economy, both in first cost and in maintenance. My fear is that, in some places, the authorities, after a period of tentative generosity, may become dismayed at the cost of providing, repairing, and renewing apparatus, and disappointed with the results of their expenditure, and so limit their financial help and organized co-operation in this work.

FIRST STAGE.

Probably far more good can be done by treatment during the early hours and days of the attack than at any subsequent period. While quarantine is certainly advisable, and serum may prove helpful, the indications for orthopaedic treatment during the first few hours and days after the onset are urgent. We have to deal with acute anterior poliomyelitis—the anterior horn cells are inflamed and poisoned. They need absolute rest. The shocks they receive from any reflex or central stimulation must definitely prejudice their chances of passing through the acute stage without destruction or permanent damage. This is the plainest pathological truth. Its practical application, then, is that we must keep the patient at rest in comfort and warmth. There must be no restlessness of mind or body, and no exposure of the skin to sensory stimulation. At the same time we have to consider the additional factor of the prevention of deformity and the posturization of muscles.

To carry out these principles in practice, we wrap the child completely and comfortably in cotton-wool or gamgee tissue and place him on a Thomas's double spinal frame, with headpiece, on a soft saddle, with the feet at right angles on footpieces, and the pelvis true. If the arms are affected they are held abducted with the elbows flexed. The child quickly settles into comfort and tranquillity. Rest of the spinal ganglia is achieved. In this form of protection, warmth, and splintage, the patient can be looked after without any disturbance, for he is lifted as a whole on the frame for nursing purposes.

The child is kept thus immobilized for at least six weeks, and much longer in serious cases. After all tenderness is gone light massage without movement is begun. In some cases we put the legs below the knee in plaster over very thick wool padding, so as to keep the feet at right angles without allowing them to become flattened and abducted. The position of the anterior superior spines is verified frequently to make sure that the pelvis remains true; for a tilted pelvis is an insidious evil, and one which tends to initiate or exaggerate serious later deformities such as scoliosis.

SECOND STAGE.

The first stage passes almost imperceptibly into the second stage, and we find that the principles of treatment to be adopted in the second stage must be applied carefully and

* Read before the Section for the Study of Disease in Children, Royal Society of Medicine, July 1st, 1922.

tentatively. Sir Robert Jones stated in his address "that every case represents a separate anatomical problem." This is profoundly true, and one may well add that the treatment of a serious case requires careful reconsideration from week to week.

The principles we work on are:

1. Posturization of the trunk and limbs.
2. Correction of deformities, if any have developed.
3. Resumption of function of the ganglion cell and affected part, induced by (a) skin stimulation by light massage, (b) re-education and commencement of native movements, and (c) locomotion without overstrain.

We apply these principles in practice carefully and in the order in which I have stated them.

1. Posturization.

The chosen posture depends upon: (a) The distribution of the paralysis, and (b) the need for safeguarding "key" muscles. In connexion with the former we protect the weak or paralysed muscles from being overstrained by their stronger opponents.

[Children illustrating the application of this principle by plaster, celluloid, and double side-irons with fixed sockets, were shown.]

We have learned to be specially careful to favour and protect certain "key" muscles. We recognize that certain muscles have dominant value in the function of both upper and lower limbs. In the upper limb these are the deltoid and the median thenar intrinsics; in the lower limb the glutei and the quadriceps.

In the upper limb, unfortunately, the deltoid and the median thenar intrinsics are the muscles most commonly paralysed and most easily overstretched. In the upper limb, then, abduction of the arm and abduction and opposition of the thumb are specially cared for, the former by an abduction splint or plaster [cases were shown in arm abduction splint], the latter usually with a small plaster "cock-up" holding the first metacarpal in relation to the rest of the hand as if it were holding a glass.

In the lower limb, on the other hand, the glutei are less frequently permanently paralysed, although the maximus is often overstretched. Until the strength of this muscle is assured, or its recovery despaired of, our aim is to prevent flexion of the hip by a plaster or celluloid splint. The quadriceps is commonly paralysed, and frequently overstretched. In the common sitting position both gluteus maximus and quadriceps are overstretched. We protect the quadriceps by a walking calliper splint.

[Ten children were shown walking in callipers for one or both legs. Three of these were old cases which had been given up as incurably bedridden.]

If there is paralysis or weakness of dorsiflexion or plantiflexion of the ankle we keep the feet at right angles by fixed callipers, or double side-irons, or in plaster or celluloid. In the latter case a large boot is worn over the splint and the round calliper ends are fitted into its heel. [Examples were shown.]

During the whole of the second stage, which may last for years, we never use any hinged apparatus. The simple abduction arm splint costing 15s., the walking calliper at £1 5s., and the double side-irons at £1, with plaster, and an occasional celluloid, satisfy the needs of the limbs.

For children with weak trunk muscles, without any actual deformity, we find it useful to supply a light spinal support. Indeed, some of our cases with very extensive paralysis, whose condition was thought hopeless, walk about with two callipers and a light spinal support. They manage to get about on their legs, and, what is extremely important, to go to school. Meanwhile the principles of posturization are being realized. Considerable muscle recovery has occurred in some of these cases. Sometimes we attach straps from the spinal support to the back of the calliper to limit the flexion of the hip where the gluteus maximus is weak, or to prevent internal or external rotation of the whole lower limb.

2. Correction of Deformity.

This is carried on in the second stage after all tenderness is over. Unfortunately many cases only reach our hospital or clinics well on in the second stage, and after deformities have developed. The correction is usually done gradually by repeated plasters. The only operation that is at all commonly performed is Soutter's operation for severe flexion deformity of the hip.

* All our splints and appliances are made in the hospital workshops.

Scoliosis.—Extreme difficulty is often raised by late cases with severe scoliosis. Lovett is emphatic in his warning as to the care that is to be taken in preventing scoliosis by the recognition of unilateral paralysis or paresis of the abdominal muscles. Other trunk muscles, of course, have their share in the causation of paralytic scoliosis. While with care much of this deformity can be prevented, once severe paralytic scoliosis has developed I do not think it is right to attempt full correction. It is so easy to do much more harm than good by corrective plaster or apparatus. One must never forget that the life of these semi-paralysed children depends on their "vital capacity," and that any corrective or retentive pressure may limit the comparatively feeble movements of respiration they possess. In applying apparatus, therefore, we are very careful to leave the respiratory movements unhampered as far as we possibly can. We endeavour to erect the trunk true on the pelvis, and we find the Munk-Jansen method, by his first stage plaster-bed, and his second stage light support, helpful in many of these cases.

[A child was shown lying on her Munk-Jansen plaster-bed, then up in the (adapted) second stage light support. She had had a very severe scoliosis in association with extensive paralysis. Treatment by these methods had proved most successful.]

3. Resumption of Function.

The time comes when the ganglion cell must be induced to start work again. Usually the return of voluntary movement is automatic and needs no special help, but where no contraction is seen to occur in a muscle which has been kept in a relaxed position for some months we begin to stimulate the ganglion cell. This we do gradually and tentatively, both through reflex paths by gentle skin stimulation and through the central nervous mechanism by re-education.

When locomotion is to be recommenced the greatest care and watchfulness are necessary. It is probably true to say that there is a universal natural law that any living tissue responds to the stimulus of strain by growing stronger, but to the excessive stimulation of overstrain by wasting and weakening. Every tissue must have its own threshold between strain and overstrain. For muscles and ligaments this law is constantly at work, and when we have to deal with a partially paralysed muscle we are careful to prevent overstrain.

Lovett makes it clear that partial paralysis of a lower limb sometimes passes into complete paralysis during the late second stage, due to overstrain in locomotion. He describes this condition chiefly with regard to the gastrocnemius. We have found the same tendency commonly at work in connexion with the quadriceps, though we have been able to prevent actual paralysis supervening, except in one case which was temporarily lost sight of. It is our practice, as I have already described, to keep the feet at right angles and the quadriceps protected by a calliper until Mackenzie's final test is fully satisfied. But even after this we find that the calliper has to be left off tentatively, and frequently have to put the patient back into the calliper for several months owing to a progressive return of the quadriceps weakness.

THIRD STAGE.

The second stage passes into the third stage when posturization followed by attempted resumption of function has distinguished the muscles that are recoverable and those that are permanently paralysed.

In the third stage our principles are further to develop the patient's capabilities, whether by stabilization of joint, transplantation of tendons, etc., or suitable appliances; but we postpone operations such as arthrodesis, until after the age of 8 or 10, and keep the patients with stiff knees walking in callipers until after their school life is finished.

[Cases were shown illustrating arthrodesis and tendo Achillis reinforcement.]

After-care Centres.

In the very scattered agricultural district which the counties of Oxfordshire, Berkshire, and Buckinghamshire constitute the problem of the prolonged supervision of these cases is very different from that in a town and much more difficult. It is impossible to expect the children to come up regularly long distances to the hospital. We have got over that difficulty by instituting local orthopaedic clinics in various market towns through the area. It is necessary to carry the out-patient department of the hospital to the patient's own district.

[Two new cases were shown to demonstrate the typical complex deformities, the methods of examination, and an outline of the programme of treatment.]

As you will have seen, we try to work on simple and economical lines. The apparatus is comparatively cheap, straightforward, does not require difficult measurements or repeated fittings, and lasts for a long time, as there are no fragile or complicated joints. The appliances enable the children to walk, and at the same time carry out the twin principles of posturization and avoidance of overstrain.

I feel that methods such as these go far towards realizing our dual aims of economy and efficiency, but doubtless there are many ways in which our methods could be improved, and I hope that the subject will be widely discussed, because I feel that its importance is great and that full knowledge of the most practical methods should be widely disseminated.

ACUTE INTESTINAL OBSTRUCTION.

BY

SIR JOHN O'CONOR, K.B.E., M.A., M.D.,

SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, LUTON, A.D. 1.

This essay has been written with the intention of inviting surgeons to take stock of present methods of dealing with the most grave acute problem in general surgery, and if any of the suggestions herein contained should prove of value in helping to diminish the incidence of acute obstruction of the bowels or in enhancing the chances of surgical relief the time and thought devoted to its composition will be more than recompensed.

Adopting the motto, "Avoid the abstract and stick to the practical," I commenced by putting the question: What is to be done in case of acute obstruction when a portion of the gut is found gangrenous? Before responding, one has to bear in mind that, from the moment the circulation of the bowel becomes impeded, splenic shock and systemic poisoning begin, and both intensify in compound ratio to the hours which pass until the obstruction is relieved. General symptoms often prove delusive guides as to the existence of this lethal combination, which seems temporarily to possess an insidious potentiality only requiring some slight surgical stimulation to unroll its effect with appalling rapidity. Whenever gangrene of intestine is met with, not only is it proof positive that the case has, for one cause or another, been sadly neglected, but there exist initial factors, poison and shock, which seriously handicap any attempt at human succour. While primary knowledge of these unpropitious facts may tend in a way to alleviate the sense of dire responsibility which everyone feels when he finds himself confronted with this tragic affliction, yet it in no way detracts from the duty to spurn finess and, even at the risk of the "dead stymie," ileus complete, to give every patient not absolutely moribund a surgical chance. Conscientious work accomplished in the shortest time¹ is the one thing most likely to snatch a victory, the masterstroke being elimination of the morbid trio—overstrain, undue manipulation, and prolonged anaesthesia.

With this profacio I will endeavour to give a reply to the above question: Concentrate attention on the extent of the gangrene, carefully scrutinize the condition of the mesenteric loop, confine the attack to what is essential, and, as every moment counts, "force the game."

I do not hesitate to state that, next to having details of likely operations in clear mental perspective, there is nothing more conducive to operative celerity than, while the patient is being prepared (always including gastric lavage), personally to superintend the selection of instruments and drains, the breaching of an adequate assortment of needles, the provision of an ample (counted) supply of sponges, towels, and some rubber tissue. A few sterilized kidney basins must not be omitted, and the apparatus must be ready for any washing or injection which may be required, the operating table warmed up, and last, and indeed not least, the help of two smart assistants must be secured.

There is also a contingency which may seriously interfere with expeditious surgery in acute intestinal obstruction, assuming previous examination fails to give an indication, a very perplexing question arises at the start—where to make the incision so as to get directly at the seat of mischief. I cannot conceive anything more demoralizing to a surgeon when entering the abdomen on a forlorn mission, to

find his energy and time sapped, at the outset, in struggling to restrain inflated intestine from bursting out through the parietal wound. If the site of lesion is not evident—and, as frequently happens, the distension is so great and the serous coat of bowels so friable that it is impossible to pass the gut methodically through the fingers in search for the constriction without causing numerous peritoneal lacerations—his position is truly pathetic, between the Scylla of traumatism plus exposure and the Charybdis of retreating without having reached the objective.

These remarks are not penned on hearsay but on dire personal experience, which incited me to publish a note in the *British Medical Journal*, November 23rd, 1918 (p. 573), on the necessity of instituting careful inquiry in every case of intestinal obstruction as to a previous attack of appendicitis, or to an abdominal operation in which the appendix might have been removed for convenience; and I urged that regardless of the time which may have elapsed (detailed revision of the patient failing to point a path) a three-inch incision should be made in the right somblunar line low enough to expose the ileo-caecal region and right pelvis where the distal ileum will usually be found implicated in adhesions. While my experience may be exceptional, it suggests the personal conclusion that, excluding the era of iodine skin disinfection and those which can be located before operation, in the majority of cases the obstruction of the small intestine will be encountered adjacent to the right pelvic brim, and that the stereotyped central incision in such instances courts disaster, as in the search for the lesion the distended semi-paralysed intestines are subjected to needless exposure and manipulation.

It is not pertinent to the context to analyse the psychology which inspires postponement of operation² in acute appendicitis until what is academically styled "the cold stage" supervenes further than to interpolate that patients so treated who escape immediate transition to the glacial state remain endowed with a nest of adhesions³ which renders them likely candidates for premature mortification by the peristaltic contortions of their own small gut. And I must add that I am unable to comprehend the mentation which complacently admits of "We'll wait until to-morrow to decide" in a case of suspected acute intestinal obstruction.

Acute Obstruction of Small Intestine.

In a number of instances in which stoppage is suddenly caused by a band or kink only a narrow ring or small knuckle of bowel is found gangrenous, and in quite a proportion of these necrosis does not extend to the fixed portion of the gut, much less to the mesentery; the fact of the circulation in the heart of the intestine remaining intact induces a hope that there might be prompt restoration of peristalsis in the tube if inclusion or excision of the moribund area could be effected without entailing subsequent obstruction by diaphragm or angulation. Acting on this hypothesis, I venture to submit a classification from the operative angle, and I trust the suggestion will be viewed merely as a humble attempt to find some means of reducing the terrible mortality—40 per cent.—which attends surgical intervention as expressed in mediate or immediate enterectomy.

A.

In cases in which one finds that a complete circle of the bowel is beyond redemption I recommend that lateral anastomosis and excision of the gangrenous gut be carried out in the following order of detail:

1. The affected zone of intestine is drawn out through the external wound, extruding a sufficiency, above and below, so as to facilitate the performance of lateral anastomosis at a convenient distance from the lesion.

2. The protruded bowel is fixed *in situ* by sponges, which are meticulously packed into the wound so as to preclude any possible regurgitation into the peritoneal cavity during subsequent manoeuvres.

3. Coils of proximal and distal healthy bowel are approximated and held in apposition by an assistant while four Triplet catgut and held in apposition by an assistant while four Triplet catgut Lembert sutures, half an inch apart, baste the apposed loops together; each stay is tied when inserted and its free ends caught in a pressure forceps.

4. An opening, by sharp scalpel, two inches in length, is then made, close to and parallel with the line of stays, into the distal gut—as no clamps are employed a kidney basin is made to catch whatever escapes—and then a pressure forceps is applied about the whatever escapes—and then a pressure forceps is applied about the centre of the free edge of the incision to act subsequently as a tractor. With a large kidney basin in position a corresponding incision is at once made into the proximal bowel, free vent is afforded for escape of contents (the more the better omen), and the centre of the free edge of this wound is similarly seized with a forceps.

5. Two assistants then make ing stays, while a continuous suture (tautly secured to each segment; the ends of the "central" stays are then cut short. The forceps previously attached to the free edges of wounds are now grasped by an assistant so as to indicate a strategic site for the insertion of two anterior "central" stays; the continuous catgut through-and-through suture is then carried on (as it approaches each stay the latter is tied and continuous suture knotted to it) until closure of the anterior segment is completed; the ends of stays are then snipped away and the whole field is washed with warm peroxide lotion, dried with bibules, and the anastomosed part is enveloped in a dry towel.

6. The gangrenous portion is then taken in hand; a catgut ligature is applied at least two inches respectively above and below the proximal and distal suspect limits, the intervening necrosed intestine is excised, and any bleeding point in the mesentery is immediately dealt with. A purse-string catgut Lembert suture is next inserted around the base of each intestinal stump; with a few snips of a scissors each stump is then freed from its mesentery just enough to render it easy for an assistant to invert it, with a dissecting forceps, into its corresponding lumen as the purse-string is being tied.

7. A jug of warm peroxide lotion (1 in 35) is again requisitioned; a general wash and brush up follows; everything is thoroughly dried, and the bowel returned. Four or five through-and-through strong silk sutures close the parietal wound, leaving room at one angle for passage of two thick silkworm-gut wisps, which are so placed as not to adhere to any line of intestinal suture.

B.

In some cases an incomplete narrow ring of gangrene results from constriction by a band, which in width more or less corresponds to that of the band itself; if this does not exceed 1 cm. and the mesenteric zone is healthy, the affected coil is drawn out through the wound and secured in place as before mentioned. Four equidistant long catgut Lembert stay sutures are then passed—skipping over the dead zone—through living proximal and distal gut; these sutures are not for the moment tied—their ends are respectively caught in forceps, and the assistants with blunt hooks retract the loops of these stays well out of the way, while a kidney basin is placed in position and a transverso incision made through the whole extent of the gangrenous area (N.B.—This incision is only made in cases where, after removal of the "external" obstruction, there is no consequent visible inflation of the distal bowel); thus free escape for contents is provided. When the flow ceases the hooks are removed from loops, the forceps grasped, and upper and lower intestine approximated. The stays are then tied and a forceps applied to each pair of free ends with which the assistants make opposing traction, while a continuous catgut Lembert suture, braced to each stay as it passes, completes the matter; the ends of stays being clipped away, the toilet, etc., is effected as in A.

C.

The most difficult case for decision is the one in which a band, kink, or twist has caused more extensive necrosis, the fixed portion of gut remaining suspect, and the mesentery apparently uninvolved. The problem then arises, can infolding or excision of gangrenous section be accomplished without leaving an obstructive diaphragm or angulation? In order to clear the perspective I wish here to mention that I cannot as yet recommend the adoption of either if the belt of gangrene exceeds a width of one inch; anything above that commands the major procedure A, but within this limit the complications mentioned can be obviated.

Three long catgut Lembert stays are inserted, as above, into the proximal and distal bowel, one along the free border and one on each side midway between this anterior stay and the mesenteric attachment. Blunt hooks are then made to pick up the loops and retain them clear of the field while a free crucial incision is made through the moribund segment. When the intestinal discharge has ceased, the loops of stays being still held aside, the four gangrenous flaps (made by crucial incision) are liberally excised with scissors. The stays are then drawn taut so as to facilitate inspection of the amount of angulation produced by approximation of the proximal and distal gut. Two similar lateral stays are next inserted close to the mesenteric line, embracing as much or as little of the peritoneal coat, above and below, as may be judged necessary to correct any likely kinking by the anterior sutures. The five stays are then tied and a continuous catgut Lembert suture applied as in B.

The part stays' take in the above procedures possibly warrants a little amplification. From beginning to end they make for rapidity and good workmanship, in that they point the line for the continuous suture, help to secure its tension, and in themselves form a strong second line of defence. They

are infinitely preferable to clamps, as they do not cause any devitalization of tissue, which, by the way, in acute intestinal obstruction is already sorely attenuated by distension and toxic infiltration. They possess a sound surgical attribute—namely, they admit of the operator seeing a bleeding vessel and tying it. They serve as excellent pliable tractors by which the operator can dominate at will the slippery-sloppy ground on which he has got to work, and consequently are the best insurance against an attack of "the tail wagging the dog" at a moment when one carries a heavy time handicap in a race for life in the most fatal of acute surgical affections.

Acute Colic Obstruction.

In this catastrophe, if the problem as to the seat of lesion is not solved before operation, it may be taken for granted that what was mentioned as a contingent complication in acute intestinal obstruction is a certain one in advanced colic obstruction, and, owing to the enormous distension associated with the latter, surgical intervention as often as not ends in a tragedy. After a certain amount of prolonged pressure and manipulation necessary to retain intestinal balloons inside the abdomen, a rather sudden and unexpected relaxation or tension occurs, which is apt to lure one on to proceed instead of heaving a rapid retreat, but which in reality is the culminating exposition of intestinal paralysis induced by the superaddition of traumatic to pre-existing splanchnic shock. The curtain then drops as the anaesthetist whispers the epilogue—myocardial liquidation has begun.

Under such circumstances it is natural that one should seek for some mode of escape before the advent of the fatal loss of spring, and I cannot see anything promising on the horizon except, in all cases in which thorough examination and careful study of the history fail to give a clue to the whereabouts of the obstruction, to make a right semilunar incision, explore gently for a few minutes, and if there is no result proceed at once with the preliminary step of closing the wound by inserting four or five long through-and-through strong silk sutures, and without knotting catch the ends of each in a pressure forceps. Then coax the left hand, supinated and extended, between the parietal peritoneum and the bowels over to the right iliac fossa, where two fingers flexed forward point the site for an incision large enough to allow the external inferior sacculature of the caecum to be drawn outside and maintained there momentarily by forceps. The semilunar wound is then rapidly closed, and a dressing applied covered by rubber tissue and a towel, and immobilized by fixation forceps.

Attention is then turned to suturing the exposed caecal sac to the margin of the iliac wound in such a manner as to preclude any subsequent backward percolation. The patient is then gently rolled over on his right side to the edge of the table, a basin is placed in position, and a stab made into the gut sufficiently large to give free vent to its contents. I have had gratifying results with this method, and whenever feasible I like to employ the external inferior sacculature for drainage; as its site is strategic, it seems anatomically adapted for the purpose, it occasionally closes spontaneously after the obstruction disappears, and it can be closed by operation without encroaching unduly on the lumen of the caecum.

The early insertion of the through-and-through silk closure sutures may require some explanation. These sutures, in place, help to prevent a rush from within, as the wound can be promptly occluded by traction on the forceps and thus diminish pernicious handling of bowels. They afford good support for any temporary packing, and their presence tends to obviate separation of layers of parietal wall during operation. Owing to internal pressure their introduction may be an arduous business, which, to save valuable time, had better be effected before the fatigue stage supervenes; and the fact of their being in affords a comfortable homeward-bound feeling, which on occasion is not to be despised. If long threads of silk are used the loops can be readily hooked away from the field so as not to cause any operative inconvenience.

It may have been observed that I advocate an incision in the right semilunar line for both acute colic and acute "intestinal" (unplaced) obstruction, the reason for doing so being that 70 per cent. of acute abdominal lesions are credited to appendicitis. If to this be added the incidence of pyloric, duodenal, and biliary affections, the ratio of involvement of the right as compared with the left abdomen must certainly stand not less than 6 to 1; and knowing that the most frequent cause of obstruction is the legacy peritoneal agglutination following infective processes and operation for their relief, the deduction is, to say the least, logical.

that, given no direct guide, the chances are greatly in favour of finding the lesion in the right abdomen. And as to the systematic search for obstruction by passing the gut through one's fingers, my experience dictates that this can be (when severe coat permits) as effectively done through a right semilunar as through any other incision. As to making a separate suitable opening in the right iliac fossa for caecal drainage, I am all in favour of it, for it appreciably diminishes the risk of subsequent virulent infection and its consequences in the large primary wound.

Peritoneal Seclusion of Stumps.

In 1903 I received my first object-lesson as to the danger of leaving raw endothelial stumps in the peritoneal cavity, in the case of a young lady on whom I performed double oophorectomy for cystic disease, and as the appendix was very much in evidence I thought it expedient to remove it. This was done by a method in vogue at that period—namely, ligation and touching the stump with a disinfectant. As there were no adhesions, the whole operation was simplicity itself. Ten days later she suddenly developed acute intestinal obstruction; the wound, under anaesthesia, was opened up, and to my intense disgust I found the stump of the appendix glued to that of the right ovary with a coil of congested ileum clutched in the adhesion. An uneventful convalescence ensued. Since then appendiceal stumps have, when possible, been buried in the caecal wall or covered with an omental plaster.

The most recent reminder occurred in a married lady on whom I performed right oophorectomy in October, 1920. As customary, the appendix, for "insurance" reasons, was also removed, and the stump interred. On June 3rd, 1921, she was suddenly seized with violent abdominal pain and vomiting, which her doctor attributed to "acute gastritis"; various enemata and purgatives were ineffectually administered during the following four days. She was brought into hospital on the morning of the fifth day: the abdomen was distended and porraceous vomiting incessant. There were no general symptoms beyond a distressed facial expression. A test enema was at once given, but without result, and as soon as the stomach was delivered of a basinful of dark green foul liquid she was transferred to the operating table. As parietal vaginal and rectal examinations gave no indication, I made the usual right semilunar incision. Immediately some coils of distended congested ileum bobbed up in the wound, which were returned by bibulo pressure; the left hand was then introduced into the right pelvis, where it found a loop of ileum bound down, after the manner of a Christmas cracker, by a tenso band about 1 cm. in breadth and 10 cm. in length, passing from below the caecum to the base of the right broad ligament. The left index finger was gently insinuated beneath the band and the strictured gut, and the former elevated (without rupture) for inspection. Then we found the silk ligature, which had been placed nine months previously on the meso-appendix, snugly encircling the band about half an inch from its upper point of fixation, affording a direct and positive proof that the band had originated in and included the stump of the meso appendix. A small caecal scar indicated the tomb of the appendix; the right ovarian stump was free and had contracted to the size of a pea. The band was excised and the gut drawn up into the wound; a belt of gangrene, corresponding to the width of the band, involved the greater part of the free zone of bowel. Stays were inserted, and as peristalsis had visibly resumed its function the necrotic segment was infolded (without incision) by stays and a continuous Lambert catgut suture. Prompt recovery followed.

Some months previous to this, while pondering over the matter of how to reduce contact to a minimum when dealing with the stump of an infected appendix, I stumbled into a very simple method of secluding the stump of the appendix and that of the meso appendix by one ligature in one peritoneal pocket, and, in passing, I may add that my colleague (Dr. Fehilly) and I have employed it in many cases and find it as useful as it is practicable.

1. The meso-appendix is ligated and the appendix isolated in the usual manner; the ends of the ligature are not cut away.

2. A curved intestinal needle is then attached to one end of this ligature and a three-insertion (two lateral and one anterior) purse-string suture is passed, at a distance of about one-third of an inch, around the base of the appendix; the anterior point of suture is purposely inserted beneath the anterior longitudinal band.

3. The needle is then removed and the ends as well as the loops of the purse-string suture are left loose and kept out of the way while the appendix is clamped at the level of the caecum, separately ligated, and cut away.

4. The ends of the "ligature suture" are then sought for, and as they are tied together (the assistant with a dissecting forceps

pushing the appendiceal stump backwards), both stumps instantly and definitely disappear from view; only two things touch the raw surface of the stump of appendix—the knife and the dissecting forceps.

The above is the first instance in which I found the stump of the meso-appendix in *flagrante delicto*, but I have often suspected its complicity in pelvic adhesion jungles; however, knowing the tendency that peritonium has to adhere to any raw surface, I think I may safely advocate burial of this stump, particularly as both it and its mate (of the appendix) can be readily interred together with the same bit of string.

Peritonization of Stump after Salpingo-oophorectomy.

After periodic attempts at rotating the ovarian or salpingo-ovarian stump downwards and suturing its face backwards on the anterior shelf of its broad ligament I have definitely abandoned the procedure, as I found it almost impossible to avoid, even with blunt instruments, the occasional formation of a troublesome intraligamentous haematoma; and, moreover, the manipulation necessary for such adjustment endangered the security of the pedicle ligature. Instead, I have adopted a much more simple and more readily applicable method, which can be always resorted to without "asking for trouble": a web about one or two inches square is excised from the omentum and plastered over the surface of the stump, and a piece of fine silk (or the ends of the ligature) is made to secure it, in bonnet fashion, around the neck of the same. In infected cases I always employ catgut instead of silk for ligation of the pedicle and for fixation of this omental "patch."

I beg leave to make a digression in stating that, irrespective of the result of any previous examination, and regardless of the "authority" who made it, whenever the abdomen of a female is opened for removal of the vermiform appendix, the opportunity should never be lost of making an internal digital examination of her uterus and ovaries, and I guarantee anyone who follows this advice, that he will be astonished at the frequency with which he will strike a coincidental lesion in these organs. For this reason it is imperative to adopt a right vertical incision when performing appendicectomy in womankind.

In conclusion, I must crave indulgence for occupying so much space with practical details, yet, acting on "the faith that is in me," it is the close study of minutiae and their application in workmanlike order which makes for operative efficiency.⁶

Memoranda:

MEDICAL. SURGICAL. OBSTETRICAL.

CHOLECYSTOGASTROSTOMY.

On July 4th, 1922, I was asked by Dr. Dykes to see a lady, aged 60, who was suffering from deep jaundice and severe abdominal pain. In December, 1921, I had removed ninety-five stones from her gall bladder. She remained well until a month ago.

On opening her abdomen I found that her symptoms were due to stricture of the common bile duct; no stones were found. It has been my practice in these cases to make an anastomosis between the gall bladder and the duodenum, or, if more convenient, between the gall bladder and the transverse colon. In the present case there were so many adhesions that neither of these situations was favourable. Bearing in mind the recommendation brought forward by Mr. C. A. Moore in the British Medical Journal of November 19th, 1921 (p. 826), I made an anastomosis between the gall bladder and the stomach on its anterior wall about an inch inside the pylorus. The result has been entirely satisfactory. The jaundice has disappeared and the pain has not recurred.

I feel it is right to add my testimony to the value of this operation because there must be many cases which would be benefited by it.

Consulting Surgeon, Kidderminster Infirmary and
Children's Hospital.

HYDROA AESTIVALE IN IDENTICAL TWINS.

If we required to prove to demonstration that a rather rare affection of the skin—known to be excited by the sun's rays—was nevertheless mainly due to congenital vulnerability of the skin, we could not wish for surer proof than to meet with the affection in identical twins, living under identical conditions, displaying identical lesions (symmetrically distributed) at the same time of year.

I have recently met with such a remarkable coincidence, and as I am not aware of any such occurrence having been published I wish to record the chief facts. The patients were twin girls, aged 11, remarkably alike in every way. They have had two outbreaks this year, each outbreak of hydroa occurring, of course, with the change of weather from dull and cool to bright and hot. They each had simultaneous and similar outbreaks last year and the year before.

Their faces are deeply freckled. There are a few vesicles on their faces and on the backs of their hands. Scars of former lesions can be found on their faces, but are more numerous and conspicuous on the backs of the hands. The lesions heal up and do not tend to recur as the girls become accustomed to summer heat and sunshine. The other children of the family do not suffer in this way, and there is no family history of the complaint. The freckles on the faces are so numerous and some of them so large and so black as to amount to serious disfigurement. At first glance the freckles reminded me of xeroderma pigmentosum, but a further inspection easily excluded such a serious diagnosis. Unna described the affection as "hydroa puerorum," doubtless because it occurred chiefly in boys in Germany. Girls now, in England at least, live more outdoor lives, and in my experience are quite as liable as boys.

As to prognosis and treatment: I could promise the cessation of outbreaks in three or four years' time and great improvement at once by treatment. Gloves were to be worn and wide-brimmed hats, and the seaside holidays taken where the aspect was east or north instead of south, as was their habit. With a southern aspect a double dose of sunlight is experienced—direct sun rays and those reflected from the sea surface.

As in the case of all bullous and vesicular eruptions care should be taken that antiseptics are applied sufficiently often to prevent infection and its resulting (preventable) scarring. At night the skin can be gently mopped with solution of carbolic acid, say 1 in 60. Then a cold cream containing boric acid for the night only. During the day a calamine lotion can be painted on. It incidentally excludes some amount of light, hides freckles, and is not itself unsightly.

London.

ALFRED EDDOWES, M.D., M.R.C.P.

THE FOETAL HEART.

It has been stated that crepitation of the foetal head bones constitutes practically the only positive diagnostic sign hitherto reported of intruterine death. The hearing of the foetal heart, on the other hand, is a very reliable sign of life, but one about which apparently even the wisest may be misled. Some years ago, on this evidence of life, two able gynaecologists roused in a hitherto childless and fibroid patient indescribable feelings of joy. I was present at the Caesarean hysterectomy next day, and shall never forget the chagrin of the surgeon as he removed a long dead and macerated foetus.

With the above as my apology, I beg to mention an expedient which has seldom if ever failed me. The chestpiece of an ordinary binaural stethoscope, as it hangs from the ears, is allowed to rest on the desired portions of the abdomen untouched by the fingers, any tendency of the chestpiece to slip being corrected by the position of the patient, complete contact being of course necessary. In this way, the otherwise unavoidable and misleading vibrations set up by the muscular tension of the hand being absent, one can say with certainty whether one hears the foetal heart or not. Doubtless to many this method is no novelty, but as a student I was left to find it out.

Reading.

DONALD E. MORLEY.

SURGEON LIEUT.-COLONEL DONALD ELCUM, I.M.S. (ret.), who died on August 8th, left £17,580 net personality. Subject to certain legacies he leaves the residue of his estate in trust for his brother and sister, and on the death of the survivor of them to Guy's Hospital for beds to be called the Charles Frederick Elcum Beds, in memory of his father, formerly a student there.

Reviews.

CARDIOLOGY.

THIS monograph by Dr. Louis Gross, entitled *The Blood Supply to the Heart*, is a valuable contribution to the literature of the subject. It contains a full and detailed description of the arterial and venous blood supply to the normal heart, with special reference to the common variations; and an account of the blood supply to the two nodes (S.A. and A.V.) and to the bundle and its branches. The author is of opinion that a distinct and specific blood supply exists for both sino-auricular and auriculo-ventricular nodes, the main bundle, the first portion of the left limb, and a large part of the right limb of the neuro-muscular system. This opinion is based on a study of one hundred hearts. A valuable chapter deals with the blood supply to the valves of the heart in its relation to the incidence of inflammation of the valves, and a most interesting description of the changes in the coronary arteries accompanying the advance of years. As the heart grows older the coronaries become more tortuous, and there is an ever-increasing left-sided vascular preponderance. Coincidentally there is an increase in the number of the ramuli telae adiposae. Dr. Gross looks on this as a most important functional and compensating unit. Relative poverty in the blood supply to the right heart is characteristic of senility and one of the dangers of advancing years. In fact, as Dr. Gross says, "a man is as old as his right coronary artery." The method used for making the anatomical investigations is described in the first chapter. Dr. Gross employed an injection of barium sulphate suspended in gelatin; from the hearts thus injected roentgenograms were obtained; they were then dehydrated in alcohol, cleared in oil of wintergreen, and finally dissected and sectioned. Coloured gelatins were also used for injection, so that the ramifications of one coronary artery could be distinguished from those of the other. A full and detailed description of the processes is given. The illustrations are exceptionally good, but their value would have been increased had some method been employed by which the various subdivisions of the coronaries and other points of interest could have been indicated. The whole subject is presented in clear and readable style, and the book is probably the best of its kind yet published.

THE heart exists for the purpose of maintaining an efficient circulation. It is essentially an apparatus designed to circulate its contents; and Dr. Sainsbury in his book, *The Heart as a Power Chamber*,² views the phenomena of the circulation from the essential dynamic standpoint and advances certain views for which he asks the consideration of his readers. He describes the aorta as a transformer interposed between the heart and the capillaries, and he discusses the mode of functioning of the aortic valve, maintaining that the structure is such as to bring about and maintain a central flow during systole, the valve never being fully opened. He claims that this is of material importance in preserving the integrity of the aorta. His detailed and reasoned criticism of the interpretations of records from the jugular vein is vitiated by the fact that he does not recognize that these tracings are records not of pressure but of volume. On page 202 the author describes an extension of fibrillation below the auriculo-ventricular sulcus into the substance of the ventricle, and regards this change as "a much more serious condition." It is evident, however, that he does not appreciate the lethal nature of fibrillation when it involves the ventricle. After carefully reading this book the question presents itself: What is the aim of the author? His answer, found on page 239, will perhaps help in appraising the work. Dr. Sainsbury says that his real objective will have been attained if "the anatomist and pathologist may be led, in the presence of the statics of death, to endeavour to reconstruct the dynamics of life; and the physician be led in like manner, in the presence of the disturbed dynamics of disease, to recall the teachings of physics and chemistry and physiology; and to endeavour to enlist them on behalf of the healing art." To quote again from the same chapter in which reference has

¹ *The Blood Supply to the Heart in its Anatomical and Clinical Aspects*. By Louis Gross, M.D., C.M. New York: Paul B. Hoeber. (Sup. roy. 8vo, pp. xvi+171; 34 figures, 5 dollars net.)

² *The Heart as a Power Chamber: A Contribution to Cardiodynamics*. By H. Sainsbury, M.D., F.R.C.P. Oxford Medical Publications, London: H. Frowde, and Hodder and Stoughton. (Demy 8vo, pp. xli+248; 23 figures, 12s. 6d. net.)

been made to "the therapeutic appeal," the following occurs: "What then are the means at our disposal to answer the appeal? They belong to the order of the medicamenta which in their wide range constitute the materia medica as embodied in the pharmacopoeias of the world." These quotations will give an idea of the author's style, which while having a charm of its own is rather too florid and ornate for dealing with a subject requiring lucid and clear presentation.

MORBID ANATOMY.

Contributions to morbid anatomy are not nowadays so common as to be passed by without a few words of special comment. And in his new book Professor OBERNDORFER¹ has achieved something out of the ordinary. He has published a series of photographs, reproduced very well by a copper process, representing the gross post-mortem appearances of various abdominal conditions. The plates are a selection from his large collection, and embrace carcinomatous and tuberculous peritonitis, intestinal obstruction, duodenal ulcers, hon-glass stomach, gastropexia, caecum mobile, megacolon and coloptosis, mesenteric infarct, and pregnancy. Several specimens of the above and of other conditions are exceedingly good, and have been used, with the aid of a projection apparatus, by the author for his lectures. Teachers in this country would find them admirably suited for this purpose.

Good though the pictures are the chief interest of the book lies in the author's comment on the anatomy of these conditions. He proves himself to be very well read in clinical medicine, and particularly so in clinical surgery. His remarks on the mobile caecum show him to be well abreast of the times. And in this connexion he makes a remark, not perhaps original, but which surgical anatomists will do well to take to heart. He points out that the position of the appendix varies greatly with variations in the mobility of the caecum. The usual textbook dissertations on the position and relationships of the appendix do not give this factor its due. Further, all who operate upon diseased appendices realize that the case of removal of that organ greatly depends on the fixity of the caecum from which it springs. Professor Oberndorfer has found Holzner's steatocyst stomach to be rare (save in infants), thus endorsing the modern radiologists' views. He believes from his post-mortem observations that acute dilatation of the stomach is due to duodenal ileus—compression by the mesenteric vessels. He has found in cases of hernia that the mesentery of the piece of bowel involved is always lengthened and frequently scarred, the scars often running as fibrous bands some considerable distance, even to the root of the mesentery. These scars he puts down to slight tears in the serosa, and cicatrization of the consequent exudate. As for the local lengthening of the mesentery he states that in old-standing cases observation will always lead to the identification of the piece usually habitant in the sac.

Professor Oberndorfer's book will well repay study on the part of those who are interested in abnormal anatomy. The post-mortem room offers unrivalled opportunity for the investigation of such problems as have been touched on in this review, and it is interesting to see that somebody is taking advantage of them.

THE FOUNDATIONS OF PSYCHOLOGY.

DR. JARED SPARKS MOORE intends his volume on the *Foundations of Psychology*² to serve as a textbook in advanced courses in general psychology and for the general reader interested in the nature and methods of mental science. The work contains matter not found in the ordinary textbook or manual, and thus fills a gap in psychological literature. Psychology presents serious difficulties to the student at the present time because there is no general agreement as to its scope, aims, or subject-matter. Naturally the author is not able to harmonize the disagreements which exist or to devise a formula which would content the various antagonists. No one could do this, and the author has his own views to develop; but he does succeed in making clear the principles and assumptions which underlie the opposing schools of thought, and his volume will undoubtedly serve to remove some of the difficulties which confront

the student, who will at least learn from it what the structuralist, functionalist, introspectionist, behaviourist, and the rest are endeavouring to accomplish in their respective spheres.

The volume is divided into three books or sections. The first is devoted to an exhaustive discussion of the definition of psychology. The view ultimately developed is that psychology should be defined as "the science of mind." By this definition the author designedly narrows the scope of psychology to the study of mental states, and gives a central and unique place to introspection as *the psychological method*. He gives full credit to behaviourism, and recognizes that it has a positive significance for psychology, but would prefer to include it in the biological sciences under the heading of "praxiology." It is improbable that the majority of psychologists would care to limit the scope of their investigations to the extent suggested, and in practice, in this country as well as elsewhere, psychology is assuming an increasingly behaviourist tendency, with emphasis on the "situation-response" relation, in which introspection plays a very small part. The middle position taken by McDougall is perhaps the most desirable in the present state of knowledge, though it is interesting to observe that the famous English psychologist has recently taken what appears to be a more conservative attitude (Prolegomena to Psychology, *Psychological Review*, January, 1922).

Book II is concerned with the "The field of psychology"; the subject is discussed under the following headings: psychology and metaphysics; the problem of science; the problem of metaphysics and its relation to science; psychology as science and as metaphysics; psychology and real life; psychology and the material sciences; the differentiation of mental from material facts; conditions of psychological description. Book III deals with the postulates of psychology, and the hypothesis of the subconscious, to which the author expresses adherence, is considered at length. Freud's hypothesis of the "unconscious" is only discussed from the theoretical point of view and the treatment of this subject is purely on academic lines.

GENERAL SURGERY.

DR. HAUBOLD, Clinical Professor of Surgery in New York University, has written a treatise entitled the *Principles and Practice of Surgery*³; it contains 2500 pages, and is issued in two volumes in a manner which on the whole does credit to the publishers, though the illustrations might be better. Those which have been reproduced from other publications are good, but the majority of the original illustrations are poor; many of the line drawings convey little information, and here and there the draughtsmanship is faulty.

Volume I is more especially concerned with the problems of general surgery, though it contains instruction for amputations and the ligation of blood vessels. The author is sometimes not altogether happy in his choice of words and terms. "Thyroidism" is quoted as an example of "the circulation of a family secretion"; "uraemia" is defined as "an accumulation of excretions"—these are surely inadequate descriptions of the conditions they purport to explain. Many pages, indeed, are marred by one or more unfortunate errors of expression. The actual surgical matter the book contains is also open to criticism. Many of the views the author puts forward are out of harmony with modern surgical teaching. The first chapter deals with wounds, and in it this remarkable passage appears:

"The leukocytes (phagocytes) perform an important office, as they absorb the destroyed cells by the production of ferments which are capable of dissolving albumen, and also produce a protective substance chemically destructive to pathogenic bacteria, which, despite the most rigid precautions, prophylactic or anti-septic, are present in wounds."

The pathology of this statement is erroneous, the method of its expression is not good, and the sweeping generalization at the end is open to serious question. It is said that the constitutional symptoms of wounds are "shock and acute anaemia." The experienced clinician is well aware of what Professor Haubold has in his mind when he makes this statement, but to the student beginning the study of surgery, the impression conveyed may well be erroneous. In discussing the treatment of wounds it is said that "the use of

¹ Bauehheile, By Professor O. Oberndorfer, (Med. 8vo, pp. 133; 12s. 6d. net.)
² Jared Sparks Moore, Ph.D., Associate Professor of Philosophy, Eastern Reserve University, Princeton: Princeton University Press; London: H. Milford, Oxford University Press. (Med. 8vo, pp. xvi + 239. 12s. 6d. net.)

³ Principles and Practice of Surgery, By Herman A. Haubold, M.D. Two volumes. New York and London: D. Appleton and Company. (Roy. 8vo. Vol. I, pp. 1316, 631 figures; Vol. II, pp. 1170, 413 figures. £45s. the two volumes.)

chemical haemostatics such as alum, vinegar, cold water, zinc chloride, etc., increases the danger of infection, because they liberate infectious organisms from the contiguous tissues and spread them into the wound area." We are unaware of any proof of this statement; the stronger haemostatics may devitalize the wound tissues and so render them more liable to infection, but it is difficult to understand how a solution can liberate infectious organisms from contiguous tissues. In a chapter dealing with the technique of cleansing the surfaces of the body it is advised that, after scrubbing with soap and water, the hands and forearms should be coated with chloride of lime made into a paste with water; while the lime is still on the skin sodium carbonate is to be applied, thus liberating chlorin, an active bactericidal agent. The application, the author says, produces a sensation of warmth, and directs that when this has ceased the paste is to be washed off with a 1 per cent. solution of corrosive sublimate. Later on he says that complete removal of the mixture is accomplished by rinsing the hands and forearms in a solution of sodium carbonate 2 per cent. before the corrosive solution is applied; the hands and forearms are then immersed in alcohol, which is rinsed off with sterile water. One wonders whether the author puts this method into daily use; if so, he must be possessed of infinite patience.

Volume II also is open to serious criticism. The section dealing with deformities and orthopaedics is a fair presentation of the subject, but there is little original matter of interest, and there are some serious inaccuracies. The chapter on spondylitis is difficult to accept as a statement of the author's knowledge and experience. We disagree altogether with the account given of the pathology; some idea of the standard of the chapter can be gained from the advice that when an abscess forms it should be "drained with the view of obviating gravitation of the products of inflammation to a distant point and secondary invasion en route."

As we have indicated, the blemishes in these volumes are, in our opinion, too numerous to warrant its acceptance as an exposition of the present state of American surgery from which surgeons all over the world are learning so much.

MENTALLY DEFICIENT CHILDREN.

The fifth edition of *Mentally Deficient Children*,⁶ by Drs. G. E. SHUTTLEWORTH and W. A. POTTS, appears at an opportune time, since public interest is greatly directed to all things connected with mental deficiency and disorder. Since the issue of the last edition the provision for the care of the defective class has been considerably extended in England by the Act of 1913, and the activities of public authorities have been increased in the United States as well as in this country. All those developments receive attention in the new edition. The descriptions of mental tests have been brought up to date, and the many advances made during recent years in the procedure for dealing with juvenile criminality are explained.

Psychotherapeutic methods in the management of emotional cases, in psychic epilepsy, and in the development of cleanly habits among defectives, are discussed, though the authors, we gather, do not consider the results obtained very conclusive; yet some improvement has been noted in respect of the last-named matter.

Lists of institutions under the Mental Deficiency Act in this country, and of similar establishments in the Dominions and in the United States, are given. Some of the American institutions, in several instances, are large: one of them can receive as many as 2,200 inmates. There are appendices containing very complete bibliographical lists and other matters of interest. The work as a whole must be commended to all interested in these subjects for the general information and the trustworthy guidance in treatment it affords. The present edition merits all the praise that has been awarded to its predecessors.

THE SNAKES OF CEYLON.

COLONEL FRANK WALL's elaborate description of the *Snakes of Ceylon* is issued by the Colombo Museum, and copies may be obtained by application to Mr. Joseph Pearson, the director

⁶ *Mentally Deficient Children, their Treatment and Training*. By G. E. Shuttleworth, B.A., M.D., and W. A. Potts, M.A., M.D. Fifth edition, considerably enlarged. London: H. K. Lewis and Co., Ltd.; Philadelphia: P. Blakiston's Son and Co. (Cr. 8vo. pp. xviii + 323; 8 figures, 21 plates. 1s. 6d. net.)

⁷ *Ophidia Tropica, or the Snakes of Ceylon*. By F. Wall, C.M.G., I.M.S. Colombo: H. K. Cottle, Government Printer, Ceylon; or the Director, Colombo Museum. (Demy 8vo. pp. xxii + 531; 1 map, 93 figures.)

of that institution. The work is dedicated by Colonel Wall to his father, Mr. George Wall, who spent a laborious and useful life in the interests—social, industrial, scientific, municipal, administrative, and political—of the colony of Ceylon. The book is prefaced by a portrait and memoir of that very distinguished man, and may be accepted as a memorial to his father by a devoted and dutiful son. The work is an exhaustive record of all that is known regarding the serpents of Ceylon down to the present time, and indications are given of the need and direction of further research.

The author, who had previously written a treatise on the poisonous terrestrial snakes of our British Indian dominion (including Ceylon), has, in addition to his own observations in India and Ceylon, made use of all the information previous writers (Poyser, Richards, A. J. Wall, Drummond Hay, and others) have contributed to this subject. The book contains full details regarding sixty-three species of terrestrial snakes found in Ceylon, and of twenty-two pelagic snakes frequenting its coasts. Each species is described systematically and exhaustively under the headings of the native name (when known), history, general characters, coloration, identification, habits and haunts, foes, parasites, food, breeding and growth, scales and teeth (illustrated), and distribution. While the information given under these categories is strictly scientific, entertaining matter of more general interest is supplied regarding the common and important serpents—for example, the python, cobra, krait, and Russell's viper (daboia).

Of more purely medical interest is the information presented at length regarding the venom of the Thanaophidia—its source, its nature, physical and chemical; its poisonous effects, local and general, and the measures necessary for dealing with them. The volume is well printed and indexed, and constitutes a valuable summary of all the knowledge which has been amassed in India and Ceylon respecting a most interesting department of natural history.

PHOTOGRAPHY IN COLOURS.

THE fourth edition of LINDSAY JOHNSON's book on *Photography in Colours*⁸ has been brought thoroughly up to date and is most comprehensive. In its general construction it is well thought out. After an opening chapter on the nature of light and colour there are chapters upon the evolution of colour photography, the sensation of colour, and so on; following this the different methods are explained—the single-plate colour processes and the three-plate and two-plate methods; colour printing is thoroughly explained, and there is a chapter on kinematography and another on colour photomicrography. An appendix, which shows evidence of careful compilation, gives many useful details about development, the after-treatment of the plates, and other photographic details; it includes also tables of exposures for various subjects.

In the author's hands, and judging from his lucid descriptions, colour photography either by the single or the three plate colour process appears to be quite simple, and the various photographic processes no more difficult to the ordinary amateur than those followed in the successful manipulation of the ordinary dry plate in ordinary photography. A very interesting chapter is that in which a comparison is made between the eye and a camera, and the retina and a colour plate. The author has written this in such simple language, and his descriptive material is so graphic, that he has made a somewhat difficult subject easy to be understood. The old saying that there is nothing new under the sun is illustrated by a note in the preface in which it is suggested that the Lumière autochrome process was in fact no new discovery, inasmuch as there is a remarkable similarity between the coloured globules in the retina of the tortoise and common fowl and the coloured starch grain of the autochrome plate. Therefore man has merely made a rediscovery of what the tortoise knew more than one million years ago. There are many useful illustrations, which are chosen chiefly from the point of view of value in making the written matter more easy to follow and understand. As a textbook upon a fascinating photographic process it achieves complete success. Nothing seems to have been omitted which is of any essential importance, and any amateur who desires information and help either as a beginner or as an advanced worker will find everything he requires.

⁸ *Photography in Colours*. By George Lindsay Johnson, M.A., I.L.D., F.R.C.S. London: George Routledge and Sons, Ltd. (Pp. 8vo. pp. xiv + 318; 14 plates, 31 figures. 7s. 6d. net.)

NOTES ON BOOKS.

THE fifth volume of the *Reports of the Episcopal Hospital*, Philadelphia, is the first published since 1916. It is edited by Dr. ASTLEY PASTON COOPER ASHURST, that versatile surgeon who makes the chief contributions to the volume. In the main the papers will be found to be reprinted from the *Annals of Surgery*, in which they first appeared either as independent articles or as contributions read before the Philadelphia Academy of Surgery. The volume contains a very varied assortment of papers on a variety of subjects, mostly surgical, but also medical, obstetrical, and dental. Amongst the contents are two long and instructive papers by Ashurst—one on empyema, commenting on the frequency of interlobar empyema and urging the need for exploratory thoracotomy in doubtful cases, the other on birth injuries of the shoulder. All in all the *Reports* are a testimony to the very lively activity of the staff of a hospital of 500 beds, representing a praiseworthy amount of creative work.

The Homeland Association, which exists for the encouragement of touring in Great Britain, has issued a series of pocket books, including a guide to the Pilgrims' Way from Winchester to Canterbury, and three volumes of footpath rambles within easy reach of London. It has now added to its list a handbook on *Homeland Prehistoric Antiquities*, written by Mr. V. G. CLARKE, formerly honorary secretary of the Prehistoric Society of East Anglia. It is well arranged, simply expressed, and contains numerous helpful illustrations; altogether it is excellently adapted to serve as an introduction to the study of a very fascinating subject for which this country, if we may accept the conclusions of the school to which the author belongs, affords almost inexhaustible opportunities. Flint implements and the way they were made are well described, the changes slowly produced in flints by weathering are explained, and the signs by which those worked by man can be recognized are detailed. There are chapters on dwellings, burial places and forts, on pottery, on bronze and early iron implements, and on the tracing of prehistoric trackways, the last a fascinating recreation to which Dr. Hubbard and his rough gavo a great impetus in their book on dew ponds. Though Mr. Clarke writes simply and briefly he is not superficial; he provides a glossary, a list of type stations, a bibliography, and an index; the only fault we have to find with him is that he does not always give sufficient particulars of where the places he mentions are and how they may be reached.

A SPECIAL number has been issued (August, 1922) of the monthly journal, *Archives Médicales Belges*, published in Brussels, to celebrate the seventy-fifth anniversary of its foundation. The *Archives* was founded in 1847 by Dr. J. F. Lemireux, who was the organizer of the medical service in the Belgian army of the revolution in 1830, and was the under and first president of the Belgian Academy of Medicine. The special number contains an illustrated article by Lemireux by Professor F. De Block, and articles on the technique of the operation for fracture of the patella by Professor Willems and on the standardization of the methods of analysing drinking water in the Belgian army by Captain Hevaerts. The remaining contents of the journal include international news from the United States, Switzerland, and France, abstracts from Belgian and foreign medical journals, and medical news.

Medical and Surgical Reports of the Episcopal Hospital, Vol. V. Philadelphia: Wm. J. Dornan. 1920. (Med. 8vo, pp. 503; 162 figures, plates.)

Homeland Prehistoric Antiquities and How to Study Them. By V. G. Clarke. Homeland Pocket Books, No. 13. London: (Pp. 140. 4s. 6d. net.)

MEDICAL AND SURGICAL APPLIANCES.

Hooked Anaesthetic Drop-bottle Collar.

Dr. F. J. STRACHAN (Troon) writes: I have been using for the last two years a simple steel collar bearing two hooks to clip on to the neck of any anaesthetic drop-bottle. I have found it particularly useful when working single-handed in midwifery practice—when once about 50 per cent. of the chloroform was spilled on the bed. Now with this simple attachment the wastage is nil, as the upright position of bottle is always assured by the catches taking a slender yet sure purchase on a pillow, the bedclothes, bed hangings, etc., or on the patient's or one's own clothing. Even surrounded with the anaesthetist's armamentarium of the operating theatre the hooked clip is always very useful. Should the clip be too large for a narrow-necked dropper a few turns of adhesive plaster round neck will ensure a rigid fit. The drawing shows the idea *in situ*. These clips have been made for me by Messrs. Baird Brothers, 97, Bath Street, Glasgow.

BOTULINUS ANTITOXIN.

IN connexion with the recent cases of botulism at Loch Marce a leaflet (Circular 342) has been issued by the Ministry of Health to sanitary authorities in England and Wales stating that the Minister considers it advisable that a supply of botulinus antitoxin should be made available for medical officers of health and medical men in case of need at several centres, in order that it may be available for immediate use in the contingency of further outbreaks of this disease occurring.

"The Minister has no reason to anticipate further outbreaks, but the gravity and mortality of the disease may, on occasion, be such that he considers that all possible arrangements should be made to provide expeditiously a supply of antitoxin if and when demanded, which could be obtained more promptly than would be the case if the only available supply were obtainable from London. He is advised that immediate use of this antitoxin is of paramount importance and the lapse of a few hours between the appearance of symptoms and the use of the antitoxin may make all the difference between its successful or unsuccessful application. Further, on the occurrence of an outbreak of botulism all persons who have consumed the suspected food should be offered a protective dose of the antitoxin (10 c.c.m. intramuscularly), even though they may not present symptoms of the disease."

Arrangements have accordingly been made for a suitable supply of antitoxin to be kept by medical officers of health at Portsmouth, Plymouth, Bristol, Cardiff, Aberystwyth, Birmingham, Oxford, Manchester, Liverpool, Carlisle, Newcastle-on-Tyne, Hull, Leeds, Nottingham, Cambridge, and Norwich, as well as at the Ministry of Health, Whitehall, London, S.W.1.

"In the event, therefore, of any outbreak of botulism [the Circular proceeds] the medical practitioner will be in a position to obtain with the least possible delay such antitoxin as he desires. This antitoxin has been prepared with great care, but there has not yet been any extended opportunity in England for its use, and therefore there has been but little experience of its therapeutic value. There appear to be good grounds, however, for hoping that it may prove beneficial in sudden cases of poisoning by *Bacillus botulinus*, the organism recently isolated in connexion with the outbreak of disease at Loch Marce in Ross-shire. It will be understood that, whilst the Ministry of Health are thus endeavoring to make this antitoxin more readily available, the responsibility for its actual use must rest solely with the medical advisers of the patient, in any and every particular instance, and the authority will no doubt consider it desirable to inform all medical practitioners in their area of these arrangements."

Enclosed with the Circular is a copy of the instructions for employing the botulinus antitoxic serum prepared by the Wellcome Physiological Laboratories at Beckenham. These are as follows:

BOTULINUS ANTITOXIC SERUM.
Instructions for Use.

Immediate Administration.—The only remedy at present known for botulism is botulinus antitoxin given by injection, and even this is unlikely to save life if the disease has progressed to a late stage. It is therefore of the greatest importance to give the antitoxin at the earliest possible moment—that is, as soon as the earliest symptoms of blurred or double vision, difficulty in swallowing, or in speech or swallowing, etc., are noticed.

Method.—The effectiveness of the antitoxin is so greatly increased by intramuscular injection that this method of administration should always be employed if possible, whereas the intramuscular method should be used. The risk of serious symptoms arising in persons highly sensitive to horse serum must be recognized, and when, in the judgement of the medical practitioner, such risk is likely to be great, he should administer a preliminary injection of a small quantity of the antitoxin (0.5 c.c.m. = 8 minims). If this produces clear evidence that the patient is, if a reaction appears in half an hour, the antitoxin should be given with particular caution, the first intravenous injection, consisting of 0.5 c.c.m. of antitoxin, being diluted with 50 c.c.m. of saline, and subsequent injections being diluted less and less till the full dose has been administered.

Dose.—Only large doses will save acute cases. The intravenous dose should be from 20 to 50 c.c.m. of the antitoxin, previously warmed to body temperature, and injected very slowly. This amount may be repeated daily if necessary.

Note.—All other persons who have consumed the suspected food, but have not yet developed symptoms, should be given a prophylactic dose of antitoxin (10 c.c.m. intramuscularly), to be followed by larger doses if necessary.

MESSRS. J. AND A. CHURCHILL announce for early publication a *Synopsis of Surgical Diagnosis*, by Mr. W. H. C. Romanis, F.R.C.S.; the fifth edition, with 48 plates, of *Pathology, General and Special*, by Professor R. Tanner Hewlett, M.D.; and the third edition of Professor Greenish's *Microscopical Examination of Foods and Drugs*.

CURRENT NOTES.

British Medical Association Dinner.

As was reported to the Representative Body last July, the Council is trying the experiment, which it hopes may become an annual event, of holding a dinner in London in connexion with the first meeting of the Council next month. The primary idea of the dinner is to do honour to any officers of the Association who may be retiring—in this case the Past-President, Professor David Drummond. But in addition the opportunity is being taken to invite other distinguished persons. Invitations have been issued in the name of the Chairman and members of the Council of the Association to some forty guests, and it is hoped shortly to announce the names of those who may be expected to be present. The Council is very anxious to make the dinner worthy of the position of the Association, and it is hoped that many members will be present. The dinner will be held on October 25th at the Grand Hotel, Charing Cross, at 7 for 7.30 p.m., and tickets (price 10s. 6d., exclusive of wine) may be obtained on application to Mr. L. Ferris-Scott, Financial Secretary and Business Manager, 429, Strand, W.C.2.

The Panel Conference.

The annual conference of representatives of Local Medical and Panel Committees will open on Friday, October 20th, at 10 a.m., at the Central Hall, Westminster. A provisional agenda paper has now been published, and the final agenda will be issued on October 13th. Committees desiring to bring forward motions are asked to send them to the Medical Secretary as soon as possible; those received at 429, Strand, by first post on Monday, October 9th, will be included in the final agenda, but relevant motions or amendments received later will be dealt with at the conference. The following documents have been circulated with the provisional agenda: (1) the annual report of the Insurance Acts Committee for 1921-22 (printed in full in last week's SUPPLEMENT; (2) a report on the organization of insurance practitioners in the event of a refusal of the terms offered by the Government; (3) the report for 1921-22 of the trustees of the National Insurance Defence Trust; (4) the Model Public Medical Service scheme; and (5) the Collective Bargaining scheme. The attention of Panel Committees is especially drawn to the report on the Organization of Insurance Practitioners, which it is hoped will be discussed fully at the conference.

Post-Graduate Demonstrations at Hereford.

It is of much interest to note the further development of post-graduate instruction under the auspices of Branches and Divisions of the Association. The Hereford Division has arranged in connexion with the University of Bristol a series of post-graduate demonstrations at the Herefordshire General Hospital on Mondays, at 3 p.m., commencing Monday, October 9th. The fee for the course is two guineas. The subjects to be dealt with in the course are stated in the notice published at p. 127 this week.

Isle of Wight County M.O.H.

An advertisement has been received for a county medical officer of health for the Isle of Wight, offering a commencing salary of £1,000 per annum, rising, by increments of £50, to £1,200. In addition to this, £50 was offered by way of travelling expenses, and as this seemed inadequate, inquiries were made of the Town Clerk. He has replied that it was never contemplated that the M.O.H. would require a motor car, as most of the travelling can be done by omnibus and train, but he has given an assurance that if the sum offered is found insufficient in the light of twelve months' experience, the question of the travelling allowance will be reconsidered. Such being the case, the advertisement has been accepted, and appears in this week's issue of the JOURNAL.

Assistant Medical Officer for Wallasey.

A Current Note in our issue of September 16th referred to the situation at Wallasey, where the town council is advertising for an assistant medical officer of health to be in clinical charge of both the tuberculosis and venereal disease work. The British Medical Association's minimum salary for an officer of this kind is £700 a year. The town council, after offering an advertisement at £600 a year which was refused, offered another at £700 rising by £25 a year to £800, and this was inserted. The latter advertisement had been sent on the authority of the Wallasey Public Health Committee, whose action was repudiated by the town council at its meeting on September 7th, and the candidates who had applied for the post on the terms approved by the Association were supplied with a copy of the resolution of the council stating that it was prepared to offer the appointment at a salary of £650 rising by £50 increments to £800, and they were asked to allow their applications to stand at the altered terms.

As it was apparent that there was a good deal of misunderstanding on the part of the Wallasey Corporation and public regarding the position taken up by the Association, the Wallasey Public Health Committee, which met on September 21st, was asked to receive a deputation from the Association and consented to do so. The deputation was

introduced by Dr. W. C. Milroy (Chairman of the Birkenhead Division), who was accompanied by Drs. A. R. and C. Wilson and Dr. P. W. Lonthart (the Secretary of the Division), together with the Medical Secretary. The deputation dealt mainly with two points: The first was that the action of the Association in fixing standards of remuneration for public appointments and trying to enforce these was not unreasonable, and that, in fact, this was the method adopted by practically all the organizations with which public bodies have to deal. The second point was that, although the Council would probably have applicants who would be willing to accept their new terms, they would be ill advised in choosing one of these candidates; because, on the one hand, the list would not be a representative one, as a good many of the best men had already withdrawn or were intending to do so; and on the other, any man appointed at the terms now offered by the Council could not receive that support and co-operation from the local practitioners which were essential if his work were to be successful. A discussion, which was on very friendly lines, then took place, and the Chairman of the Committee, Dr. J. McMillan, said that what the deputation had laid before the Committee would be reported to the Council at a future meeting and that the result must necessarily depend to a large extent on the way in which the candidates for the post backed up or failed to back up the position taken up by the Association. Dr. Milroy thanked the Committee for receiving the deputation, which then withdrew.

A very considerable proportion of the candidates who are known to have applied have already informed the Medical Secretary that they have withdrawn their applications and cordially support the action taken by the Association in trying to improve the conditions of employment of Public Health medical officers.

Another Aspect of the Economy Question.

As was shown in the Current Note last week headed "Five School Medical Officers' Salaries," some public authorities are beginning to realize that there are limits to the extent to which they can safely carry "economy" in medical salaries. The *Poor Law Officers' Journal* states that the St. George's Relief Committee, in reporting to the Southwark Guardians a vacancy in the office of Medical Officer for No. 5 District, reminded the Board that in response to recent advertisements for a local medical practitioner to fill this vacancy only one application was received, and it had been ascertained that the local doctors regarded the remuneration of £160 per annum as inadequate, the district being one of the heaviest in the union. The work was now being carried out under a temporary arrangement at the rate of 5½ guineas a week, and as it was obvious that it would be impossible to obtain the services of any medical practitioner of high reputation at the rate of £160 per annum, the Committee recommended that, subject to the consent of the Minister of Health, a salary of £250 should be offered. The Committee's report was adopted.

Division and Branch Membership.

At its meeting on September 20th the Propaganda Subcommittee had before it a return of the membership of each Division and Branch in Great Britain and Ireland. The Subcommittee directed that its congratulations should be sent to the following bodies, which showed the highest membership percentages: The Nuneaton and Tamworth, Newcastle-on-Tyne and North Northumberland Divisions; and the North of England, Staffordshire, and East York and North Lincoln Branches.

Association Notices.

COUNCIL, 1922-23.

VACANCY.

Notice is hereby given of the following vacancy in the membership of the Council:

Indian Group, comprising the Assam, Burma, Ceylon, Hyderabad and Central Punjab, and South Indian and Madras. Resignation of Lieut. Colonel R. H. Elliot, I.M.S.(ret.).

Under By-law 54 (2) the Council is empowered either to fill the vacancy itself or cause it to be filled by means of an election by the Body authorized to elect, and has decided to adopt the latter course in the present case.

Nominations must be signed by not less than 3 Members of any Branch in the Group, and must be in the following form, or in one to the like effect, and should be received by the Medical Secretary not later than Saturday, November 25th, 1922:

COUNCIL, 1922-23.

NOMINATION FORM FOR ELECTION OF A MEMBER BY THE GROUPED INDIAN BRANCHES.

By Not Less than 3 Members of the Grouped Indian Branches.

We, the undersigned, hereby nominate of (Full name and address to be given) for election by the Assam, Baluchistan, Bombay, Burma, Ceylon, Hyderabad and Central Provinces, Mesopotamia, Punjab, and South Indian and Madras Branches as a Member of the Council of the Association for the Session 1922-23.

Signatures and Addresses of Nominators

Branch(es)

Date 1922.

The election, if a contest occurs, will be by VOTING PAPERS, containing the names of all duly nominated Candidates, issued from the Head Office, 429, Strand, London, W.C.2, to each Member of each Branch in the Group.

ALFRED COX, Medical Secretary.

CHANGES OF BOUNDARY.

Mid-Essex and North-West Essex Divisions.

THE following change has been made by the Council, and takes effect as from the date of publication of this Notice:

That the area of the North-West Essex Division be added to that of the Mid-Essex Division, the new Division to be known as the "Mid-Essex Division."

BRANCH AND DIVISION MEETINGS TO BE HELD.

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION.—A meeting of the Bournemouth Division will be held at Bournemouth on Thursday, October 19th, when a British Medical Association lecture will be delivered by Dr. J. A. Ryle.

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—A meeting of the Sunderland Division will be held at 48, John Street, on Tuesday, October 3rd, at 8.15 p.m. Business:—Report of Representative at Annual Representative Meeting. To consider the following midwifery tariff: (1) No fee less than two guineas to be charged in any midwifery case; (2) the midwifery fee includes subsequent attendance for not more than fourteen days; (3) where a house in the midwifery tariff list is tenanted a reduction may be made in the fees. Report of Scientific Subcommittee. Memorial to the late Dr. Middlemass. Correspondence. Any other business.

SHERIFFSHIRE AND MID-WALES BRANCH.—The forty-seventh autumn meeting of the Shropshire and Mid-Wales Branch will be held at the Royal Salop Infirmary on Tuesday, October 10th, at 3.30 p.m., when the President, Dr. Glyn Pigott, will take the chair. Agenda: Election of new members. Correspondence on appointment of medical officer to borough police. Address by the President, entitled "Various abnormalities met with in a series of eleven hundred cases of midwifery, with special reference to placenta praevia and its treatment." A council meeting will be held at 3 p.m. By kind invitation of the President, tea will be provided. The annual dinner will be held at the Masonic Hall, College Hill, at 6 p.m. Morning dress will be worn. Tickets, 10s. 6d.

SOUTHERN BRANCH.—The following meetings of the Southern Branch will be held at the South-Western Hotel, Southampton, at 2.30 p.m., when addresses will be given:—Thursday, December 14th, 1922: "The prevention and conservative treatment of the septic gangrene," Mr. W. Sampson Handley, M.S., F.R.C.S., the surgeon to Middlesex Hospital. Thursday, March 22nd, 1923: "The diagnosis and treatment of cholecystitis and gall stones," Dr. Arthur F. Hurst, physician to Guy's Hospital. Members are earnestly requested to make a special effort to attend the meetings.

SUFFOLK BRANCH.—A meeting of the Suffolk Branch will be held at Ipswich on Friday, October 27th, when an address will be delivered by Dr. G. C. Anderson, Deputy Medical Secretary, on "The B.M.A.—its failings, its achievements, and its possibilities." Sir Henry Gauvain will also read a paper.

SUFFOLK BRANCH: SOUTH SUFFOLK DIVISION.—A meeting of the South Suffolk Division Chamber, County Hall, Ipswich, on 3.30 p.m. of Report of (see SUPPLEMENT, July 29th, 1922). Dr. H. V. Mitchell. Short address by Dr. H. V. Mitchell, bacteriologist, on the bacteriology of the County Council. Particular reference to the diagnosis of a demonstration in the County Laboratory of microscopic specimens and cultures. Tea will be provided.

SUSSEX BRANCH: BRIGHTON DIVISION.—A meeting of the Brighton Division will be held at the Queen's Road Dispensary on Monday, September 25th, at 8 p.m., for the purpose of report of the Executive Committee and of the Division to pass the following resolution:

That the Council be requested to consider the advisability of making all elections to Council and Central Committees triennial instead of annual as at present.

Arrangements for coming session. Election of Deputy Representative in place of Dr. L. A. Parry, resigned. Dr. A. M. Daldy will read a short paper on "Sudden blindness in one eye." The Brighton Division has arranged a series of clinical meetings at the various hospitals in the town, particulars of which are given below. The meetings are on Thursday afternoons and commence at 4 p.m. Tea will be provided at 3.45 p.m. Members are very cordially invited to attend without charge these demonstrations, which have proved such a success in past years. For non-members of the Association there will be a charge of 1 guinea for the series. *List of Clinical Meetings.*—October 19th, 1922, Royal Sussex County Hospital; November 16th, Children's Hospital; December 14th, Royal Sussex County Hospital. January 18th, 1923, Lady Chichester Hospital; February 15th, Royal Sussex County Hospital; March 15th, Eye Hospital; April 19th, Royal Sussex County Hospital; May 17th, Children's Hospital; June 21st, Royal Sussex County Hospital.

YORKSHIRE BRANCH.—A meeting of the Yorkshire Branch will be held at the Grand Hotel, Scarborough, at 2.45 p.m., Saturday, September 30th, when there will be a demonstration of specimens and papers.

YORKSHIRE BRANCH: HARROGATE DIVISION.—A meeting of the Harrogate Division will be held at Y.M.C.A., Harrogate, on Saturday, October 7th, at 5 p.m., when Dr. Gordon Holmes will deliver a British Medical Association lecture on "Some of the clinical manifestations of tabes," which will be illustrated by lantern slides.

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH: HEREFORD DIVISION.

Post-Graduate Demonstrations.

Post-graduate demonstrations have been arranged by the Hereford Division, in connexion with the University of Bristol, at the Herefordshire General Hospital, at 3 p.m. on successive Mondays, September 25th, 26th, 27th, 28th, and 29th. Members of the British Medical Association who desire to attend should communicate with the Secretary of the Hereford Division, Dr. Herbert Jones, Tower Road, Hereford. The fee for the course is two guineas. The subjects are:

Modern Treatment of Diabetes, by Dr. J. A. Nixon, C.M.G.

Diagnosis and Treatment of Common Gastric Disorders, by Mr. A. Rendle Short, F.R.C.S.

Diagnostic Value of Cerebro-spinal Fluid Examinations, by Dr. G. Badfield.

Diagnosis and Treatment of Toxaemia of Pregnancy, by Dr. Walter Swayne.

Diagnosis and Treatment of Gall-bladder Diseases, by Mr. T. Cartwright.

Normal and Acquired Resistance to Disease, by Professor Walker Hall.

Correspondence.

Report of Insurance Acts Committee.

SIR,—I note with much satisfaction that the Insurance Acts Committee in their "Recommendation E" (SUPPLEMENT, September 23rd, p. 117) have definitely adopted the proposal of the West Sussex Panel Committee of a conference between lay and medical workers under the Insurance Act. The necessity for this proceeding, which I recommended in the JOURNAL nearly three years ago, is surely obvious. The interests of all workers under the Act are in the main identical—namely, to promote the best possible services for the insured, with greatest possible satisfaction to all workers, at the least possible cost to the taxpayers, who are incidentally our private patients, and ourselves.

Now, I have before me a monthly circular letter from the Medical Secretary, dated March, 1922, wherein, under "Suggestions for Divisional meetings," joint meetings are recommended with "dentists, pharmacists, veterinary surgeons, and public authorities concerned in health matters." Surely if such meetings are desirable, a conference between parties who have actually been engaged in the same work together for ten years is long overdue. By such conference many mutual misunderstandings may be removed and mutual difficulties explained. It is the only way by which that atmosphere of good will may be induced which is so essential, and which was conspicuously and disastrously lacking in 1912. We should have no difficulty in convincing our opponents that a cheap and bad service is no more to their interests than our own, and they will explain to us their difficulties, which are very real, as any one who studies both sides of the question knows. There are society officials who delight in baiting doctors, and there are doctors who deliber-

ately create difficulties for these officials. An agreement between us is the only barrier possible against the absolutely despotic power now vested in the Minister of Health, who is able to issue regulations having the force of Acts of Parliament, and, as a single individual, may, if prejudiced, be far more dangerous than the old Commissioners.

There is but one criticism to be made on "Recommendation E." No mention is made of representatives of "Clerks of Insurance Committees." These were definitely and adversely included by me in the West Sussex motion. At an Insurance Committee meeting the clerk is almost always the best-informed man present; he is, in fact, the only man who absolutely specializes in that particular work alone. Privately both doctors and representatives of approved societies seek his advice, and he has intimate knowledge of the difficulties—and, I must add, delinquencies—of both, and of defects in administrative details which might be remedied with advantage and economy. The clerks have their own association conferences, and journal, *The Naotic*, and I have reason to believe that the continual neglect hitherto to consult these experts on matters intimately concerning them is resented by the clerks. A conference without some representatives of their association would be most incomplete, and in view of their intimate acquaintance with just those matters with which doctors are unfamiliar they would be particularly helpful to us.—I am, etc.,

Chichester, Sept. 21th.

G. C. GARRATT.

Organization of the Profession.

SIR,—There are ominous signs that the friendly societies intend to fight for increased control over panel practitioners and there is also reason to think that the Ministry of Health will to a certain extent (because of such societies' political power) be amenable to the pressure which will be used.

Fortunately, the more senior panel practitioners know well enough, from past experience, what increased control will mean, and I think they may be trusted to resist even to resignation; but what about the younger men, and especially all the men who will be qualified within the next two or three years? I do not know if anything is being done to "educate" these men, but if not, can the Insurance Act Committee start at once an intensive crusade, and by means of lectures or addresses to students point out the disastrous effects of such control? One can easily imagine how a recently qualified man, without much capital, could be inveigled into accepting an appointment under a large friendly society unless he was shown the other side of the picture. Prevention is better than cure and time is of importance.—I am, etc.,

Plymouth, Sept. 22nd.

S. NOX SCOTT.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following notifications are announced by the Admiralty: Surgeon-Commanders W. W. D. Chilcott and R. F. P. Cory to the Royal Sovereign on recommissioning, C. T. Baxter to the Courageous. Surgeon-Lieutenant-Commander G. C. Green to the Dolphin, temporary.

ROYAL ARMY MEDICAL CORPS.

Colonel Don's J. Collins, C.M.G., late R.A.M.C., to be Major-General vice Major-General Sir George B. Stanistreet, K.B.E., C.B., C.M.G.; Lieut.-Colonel (temporary) Colonel E. T. Inkson, V.C., D.S.O., from R.A.M.C. to be Colonel, vice Colonel D. J. Collins, C.M.G.; Major T. J. Potter, O.B.E., is placed on the half-pay list on account of ill health contracted on active service; Captain R. R. Thompson, M.C., to be acting Major, December 13th, 1919 to May 3rd, 1921; Captain J. H. Hoag, M.C., retires receiving a gratuity; Temporary Captain F. W. Harlow relinquishes his commission and retains the rank of Captain.

ROYAL AIR FORCE MEDICAL SERVICE.

Flight Lieutenant J. Paxton relinquishes his temporary commission on ceasing to be employed.

TERRITORIAL ARMY.

ROYAL ARMY MEDICAL CORPS.

The following officers having attained the age limit are retired, and retain their rank except where otherwise stated: Lieut.-Colonels J. Howard-Jones and E. C. Stack, T.D., with permission to wear the prescribed uniform. Major (Brevet Lieutenant-Colonel) H. A. Leebod, T.D., August 12th, 1922, and is granted the rank of Colonel, with permission to wear the prescribed uniform (substituted for notice in the London Gazette, August 12th, 1922, of Murray, and is granted the rank of

show his commission, and is granted the rank of Lieutenant-Colonel, with permission to wear the prescribed uniform.

Major H. H. B. Cunningham, T.D., resigns his commission and reverts to the Regular Army Reserve of Officers (Royal Irish Fusiliers), and is granted the rank of Lieutenant-Colonel.

G. F. Wilson to be Captain, with pay and allowances of Lieutenant.

VACANCIES.

- BIRMINGHAM:** MOSLEY HALL CONVALESCENT HOSPITAL FOR CHILDREN.—Honorary Acting Surgeon.
- CLARE HALL SANATORIUM AND HOSPITAL, South Mims.**—Assistant Medical Officer (male). Salary, £350.
- LYNELINE HOSPITAL FOR CHILDREN, Southwark, S.E.**—Physician to Outpatients (honorary).
- GATSFIELD MENTAL HOSPITAL, Stanningtoo.**—Assistant Medical Officer (male). Salary, £500 per annum, rising to £520.
- GRIMSPY COUNTY HOSPITAL.**—Assistant to the Medical Officer of Health. Salary, £500 per annum.
- HONG-KONG UNIVERSITY.**—Professor of Medicine. Salary, £280 per annum, rising to £1,000.
- HOSPITAL OF ST. JOHN AND ST. ELIZABETH, 40, Grove End Road, N.W.8.**—Bacteriologist and Pathologist. Honorarium, 50 guineas per annum.
- HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.**—(1) House-Surgeon; (2) House-Physician and Assistant Casualty Officer. Salary, £50 for six months and £2 10s. laundry allowance each.
- HUNDESFIELD ROYAL INFIRMARY.**—Junior House-Surgeon. Salary, £200 per annum.
- HULL ROYAL INFIRMARY.**—Honorary Radiographer.
- IPSWICH: EAST SUFFOLK AND IPSWICH HOSPITAL.**—(1) General Surgeon; (2) House-Surgeon. Salary, £150 per annum.
- ISLE OF WIGHT COUNTY COUNCIL.**—County Medical Officer. Salary, £1,000 per annum, increasing to £1,200.
- ITALIAN HOSPITAL, Queen Square, W.C.**—Honorary Surgeon for the Throat, Nose, and Ear Department.
- TANAKA COUNTY EDUCATION AUTHORITY.**—Assistant Medical Officer. Salary, £500 per annum.
- LONDON HOMOEPATHIC HOSPITAL, Great Ormond Street, W.C.**—Third Anaesthetist. Honorarium £50 per annum.
- MANCHESTER CITY.**—Second and Third Assistant Medical Officers at the Mousall Fever Hospital. Salary, £300 and £250 per annum respectively and bonus.
- METROPOLITAN ANTHURNS BOARD.**—Medical Superintendent at the Leadenhall Mental Hospital, King's Langley. Salary, £800 per annum, rising to £250, with unfurnished house and bonus.
- MIDDLESEX COUNTY COUNCIL.**—Dental Officer. Salary, £400 per annum, rising to £500, together with war bonus.
- PADDINGTON GREEN CHILDREN'S HOSPITAL.**—(1) Physician to Skin Department; (2) House-Physician; (3) House-Surgeon. Salary at the rate of £150 per annum each for (2) and (3).
- PRINCE OF WALES GREENHAY HOSPITAL, Tottenham, N.**—Honorary Anaesthetist.
- QUEEN'S HOSPITAL, Road, E.**—(1) House-Surgeon; (2) C.
- ROCHESTER: ST. BARTHOLOMEW'S HOSPITAL.**—Resident House-Surgeon. Salary at the rate of £250 per annum.
- ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.1.**—(1) Assistant Surgeon to the Ear, Nose and Throat Department. (2) Assistant Anaesthetist in the Obstetric and Gynaecological Unit; honorarium, £100 per annum. (3) Casualty Officer; salary, £103 per annum.
- ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, Great Portland Street, W.**—Two Honorary Radiologists.
- SOUTHAMPTON COUNTY BOROUGH.**—School Dentist. Salary, £500 per annum, rising to £600.
- SOUTH LONDON HOSPITAL FOR WOMEN, Clapham Common, S.W.**—Temporary Assistant Physician (female).
- STIRLING EDUCATION AUTHORITY.**—Assistant School Medical Officer. Salary, £500 per annum.
- SUNDERLAND ROYAL INFIRMARY.**—(1) House-Physician; (2) House-Surgeon (male). Salary, £200 per annum each.
- SWANSEA COUNTY BOROUGH.**—Lady Assistant Medical Officer. Salary, £500 per annum, rising to £600.
- WARRINGFIELD: COUNTY COUNCIL OF WEST RIDING OF YORKSHIRE.**—Chief Tuberculosis Officer. Salary, £750 per annum, rising to £800.
- WHITECHAPEL PARISH, Valence Road Infirmary.**—(male) at the
- CHESTERFIELD FACTORY.**—appointments
- to announced: Dr. Burnley, North (Lanc.)** Nottingham.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

- PINTO-LEITE, Hubert, B.A., M.R.C.S., L.R.C.P.** Honorary Anaesthetist, Royal Dental Hospital, Leicester Square, London, W.C.
- SEWELL, William A., B.Sc., M.B., Ch.B.** has been appointed Visiting Surgeon to the Victoria Infirmary, Glasgow, in lieu of Mr. Farquhar Macrao, transferred to the Western Infirmary.

DIARY OF SOCIETIES AND LECTURES.

- NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's General Hospital, Tottenham.**—Thurs., 4.15 p.m., Sir Archibald Reid: X-ray Examination of the Pyloric End of the Stomach and its Vicinity.
- ROYAL SOCIETY, Section of Pathology.**—Thurs., 5 p.m., Dr. Victor Bosney: On the development of the operation. Dr. Giles will also show a specimen of large fibrous developing in the cervical stump after subtotal hysterectomy.
- ST. JOHN'S HOSPITAL, 49, Leicester Square, W.C.**—Thurs., 5 p.m., Chos. Griffith: The Elementary Lesions of Skin Diseases.
- POST-GRADUATE COURSES AND LECTURES.**
- London Lock Hospital (St. Dean Street, W.1).**—Mon., 5 p.m., Mr. Charles Gibbs: Anterior and Posterior Urethritis. Wed., 5 p.m., Mr. F. Juler: The Commoner External Venereal Diseases of the Eye.
- (283, Harrow Road, W.9).**—Wed., 5 p.m., Mr. Ernest Lano: Ante- and natal Syphilis.

MANCHESTER ROYAL INFIRMARY.—Tues., 4.15 p.m., Dr. A. Ramsbottom: Pulmonary Tuberculosis. Fri., 4.15 p.m., Dr. E. S. Reynolds: Brain Tumour.

OXFORD: RADCLIFFE INFIRMARY.—Mon., 10.30 a.m., Pathological Specimens; noon, Medical Cases; 2.30 p.m., Dr. Waters: Rheumatism; 4.30 p.m., Dr. Collier: Arterio-sclerosis. Tues., 10.30 a.m., Surgical Cases; noon, Pathological Department; 2.30 p.m., Mr. Dodds Parker: Gall Stones; 4.30 p.m., Dr. Gibson: Chronic Bronchitis. Wed., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Thurs., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Fri., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Sat., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Sun., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Mon., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Tues., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Wed., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Thurs., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Fri., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Sat., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis. Sun., 10.30 a.m., Dr. Tarrant: Chronic Bronchitis.

British Medical Association.

OFFICES AND LIBRARY, 429, STRAND, LONDON, W.C.2.

Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.

LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded, if desired, on application to the Librarian, accompanied by Is. for each volume for postage and packing.

Departments.

London. Telephone number for all Departments: Gerrard 2630 (9 lines).

SCOTTISH MEDICAL SECRETARY: 6, Rutland Square, Edinburgh. (Telephone: 4361 Central).

Frederick Street, Dublin. (Telephone: 4737 Dublin.)

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notices not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTH.

ELLIS.—August 1st, at 63, Hagley Road, Edgbaston, Birmingham, the wife of F. W. Ellis, M.D., F.R.C.S., of a daughter, "Margaret Wendy."

MARRIAGES.

COLL—ALCOCK.—On September 20th, J. McMurray Coll, F.R.C.S.E., of Onohunga, N.Z., to Doris Elizabeth Alcock, M.B., B.S., second daughter of J. Simpson Alcock, J.P., of Gaywood, Mansfield, Notts.

YORKE—WILSON.—On the 18th of September, Francis C. Yorke, M.B., B.Ch., of Edgeworthstown, second son of the late Dr. and Mrs. Yorke of Granard, co. Longford, to Sister Bertha Wilson of St. Dunstan's, London, fourth daughter of the late Dr. Thomas Wilson and Mrs. Wilson of Edgeworthstown.

DEATH.

HONOR.—On September 21st (suddenly), at Dr. Hickey's, Gainford, Peter Lodge, M.B., C.M., of 87, Jesmond Road, Newcastle-on-Tyne, late of Chadwick House, West Hartlepool.

British Medical Journal.

SATURDAY, SEPTEMBER 30TH, 1922.

THE PREVENTION OF STILLBIRTHS AND NEO-NATAL DEATHS.

THE discussion at the Glasgow meeting of the British Medical Association on stillbirths and neo-natal deaths (reported in full this week) followed closely along the lines which had been sketched in the JOURNAL,¹ and it reached the importance which had been anticipated there. Although causation and pathology were constantly in evidence during the proceedings, it is no exaggeration to say that the most impressive note was struck in connexion with prevention. Over and over again the large gathering which had come together in the Section of Obstetrics and Gynaecology responded to the suggestion of life-saving on an extensive scale which was more than hinted at by the various speakers. So far as the trend of the discussion was concerned, an equally appropriate title for it would have been "Foetal Life Preservation," and in the end these words or something equivalent found their way into the resolution which was adopted by the Section and sent on to the Council of the Association.

The introductory remarks by the President (Professor Ewen J. Maclean of Cardiff) emphasized the national importance of fertility and the saving of young lives. Dr. J. W. Ballantyne of Edinburgh opened the debate with a communication in which he sketched (but necessarily in brief) the present position of knowledge in respect of the causes, pathology, and prevention of ante-natal, intra-natal, and neo-natal death. It was a coincidence that when the British Medical Association last met in Glasgow, thirty-four years ago, the Obstetric Section had dealt with intrauterine death; the subject was introduced then by the late Sir Alexander Simpson, and leading British and American obstetricians joined in the discussion. The contrast between then and now was striking, especially in the absence (in 1888) of the idea of supervising all pregnant women in the interest of the few who were in danger of having stillbirths; preventive medicine has made great advances since then.

In his survey of the whole subject Dr. Ballantyne touched upon many matters of interest and upon some of controversy. He put in a cogent plea for the adoption of the word "transanimation" for the passage of foetal into post-natal life; his argument for abandonment of the present-day significance of stillbirth (as equivalent to dead-birth), although well founded, is not so likely to be acted upon in view of the stereotyping of the new usage by the Central Midwives Boards of England and Scotland. When he came to speak of the causation and pathology of stillbirth he was able to point cheerfully and with high appreciation to the results of the co-ordinated research work recently carried out under the Medical Research Council in various centres in Great Britain; and several of the research pathologists who followed him in the discussion showed how good and productive that work had been. He placed before the Section a few of the many remaining problems in ante-natal pathology when he asked: What was the mechanism of ante-natal as compared with post-natal death (for example, in asphyxia)? How were the changes associated with *post-mortem* maceration to be distinguished from those due to the causes of the death and subsequent maceration? What was the rôle of the

placenta? and How were all the phenomena affected by the fact that the uterine interior was free cavity? There was much work pathologist waiting to be done, and only a few tasks have been referred to. Dr. Ballantyne said that he was not offering an ordnance survey map on a generous scale of the territory of ante-natal disease and death—he was merely blazing a trail through a part of the country. It was when he came to speak of the results of ante-natal clinical supervision and treatment in the prevention of ante-natal, intra-natal, and neo-natal death that a note almost of triumph began to be heard in his address; and there was more than a touch of the dramatic when he stated that expectant mothers in Edinburgh who were free of the venereal diseases and had been adequately supervised in their pregnancy had a stillbirth rate of 6 per 1,000, whilst those who suffered from the venereal diseases and who had received no ante-natal supervision or treatment had one of 60 per 1,000. In a remark "aside" he noted the coincidence that the worst rate (606) should suggest the means (salvarsan) for its own reduction.

Dr. Eardley Holland dealt with the subject of intra-natal death, a matter for which his recent valuable work (mentioned not long ago in this JOURNAL²) specially fitted him. It was a pity that the impish behaviour of the lantern took away some of the effectiveness of the demonstration which he gave of the results of head pressure in the production of tears of the tentorium cerebelli and cerebral hæmorrhage during the act of birth; but Dr. Holland established clearly the frequency of this cause of intra-natal death in the specimens which he had examined. There was the note of hope in his communication also, for head pressure can be prevented, and in what he called the "tactics" of stillbirths prevention—namely, the thoughtful management of each labour, with the interests of both child and mother in view—there is the opportunity of much foetal life saving. Professor Louise McIlroy treated very ably the subject of "Foetal death due to toxæmia," and she also made a strong appeal for the wide adoption of ante-natal care as a means of lessening the frequency of stillbirths. Her part in this year's discussion pointed another contrast with the debate on intrauterine death in 1888; on that occasion no medical woman spoke.

Dr. F. J. Browne spoke with authority upon a subject which he had made specially his own—"Neo-natal death." The meeting was quick to recognize the behind the lantern demonstration which he gave of a vast amount of research work; and the publication of his contribution in full in our present issue will be welcomed by many. He laid special stress upon the fact which he had discovered, that the absence of naked-eye changes alone was quite insufficient to exclude neo-natal syphilis; recourse must always be had to microscopical examination. What he had to say about the intra-natal development of pneumonia neonatorum in labours in which early rupture of the membranes had occurred was arresting, and suggested the possibility of yet other microbic infection arising during the course of delivery. Still more startling was the statement that a pneumonia thus acquired might prove fatal to the infant before its transit through the birth canals was completed and so be a cause of stillbirth as well as of neo-natal death. Dr. J. N. Cruickshank also compressed a great deal of research into his paper on "Syphilis as a cause of ante-natal death"; he was dealing with a vast quantity of material, both clinical and pathological, made available in connexion with the work of the magnificent Royal Glasgow Maternity Hospital. Dr. Gilbert I. Strachan of Cardiff was dealing with a peculiarly difficult subject.

¹ BRITISH MEDICAL JOURNAL, July 1st, 1922, p. 19.

³ Ibid., March 25th, 1922, p. 463.

—placental changes in relation to foetal death—but his contribution, like the others, excited and thoroughly deserved lively interest.

Many noteworthy remarks were made by the speakers (eight in number) who took part in the discussion which followed the reading of these papers, although there was perhaps a tendency to branch off upon the fate of the "aftercoming head" and leave out other important questions. There could, however, be no division of opinion as to the practical value of the morning's discussion. The dominant note, sounded again and again by various speakers, was this: stillbirths are largely preventable, and the chief method of their prevention is ante-natal supervision and care. The note of prevention was still sounding on the following day, when eclampsia engaged the Section's attention.

ARTIFICIAL PNEUMOTHORAX.

The Tuberculosis Committee of the Medical Research Council has issued a Report¹ by Dr. L. S. T. Burrell and Dr. A. Salusbury MacNalty on the treatment of pulmonary disease by inducing a pneumothorax. The authors have brought together the chief scientific and practical considerations that are now available in profusion for "making judgement of the remedial value of 'artificial pneumothorax'—that method of treating disease of a lung by giving it controllable periods of rest from respiratory movement." Radical though this treatment is, it is not new. Dr. Allan K. Krause has recently pointed out that it is more than 2,000 years old, and in Section 59 of the second book *On Affections*, reproduced in Littré's bilingual text of Hippocrates, the following passage occurs: "If this affection results from a wound, or, as sometimes happens, from an incision for empyema, one should attach a pipe to a bladder, fill the bladder with air, and send the air into the interior of the chest." Dr. Krause concludes that this therapeutic method was actively practised by the Hippocratic school, and it is not likely that the passage just quoted could have been the reflection of speculative considerations only.

The treatment was revived in 1821 by Dr. James Carson of Liverpool. Some sixty years later Professor Forlanini of Pavia laid the modern foundations of this treatment, which has since steadily gained ground and is now counted among the greatest advances made in the treatment of severe pulmonary disease. The amount of work in this field during the past twenty years is prodigious, and the publications concerned therewith have become so numerous that the Medical Research Council has done well to issue at the present time a survey, both comprehensive and critical. As pointed out in the introduction to the Report, "it is of the first importance that results of physiological experiment and of professional experience should be gathered as fully as possible, not only with a view to giving a proper basis of support for this operative procedure, but no less with a view to aiding the accuracy by which the most suitable cases for the treatment can be recognized and selected."

The Report consists of two parts. In the first, Dr. Burrell discusses practically every aspect of the subject, from its history to the after-effects of treatment, and gives a summary of his first 150 cases. Patients with rapidly progressive disease and with a low power of resistance benefit little; on the other hand, for patients whose power of resistance is high, sanatorium or other

medical treatment is alone sufficient to arrest the disease. It is in the intermediate class, presenting the disease in a subacute form, that treatment by the production of artificial pneumothorax may do good, provided the healthier lung is not too extensively involved. The risks of artificial pneumothorax are so small, and the chances of the disease spreading are so great, that in Dr. Burrell's opinion all patients in this stage of the disease should at least be given the opportunity of pneumothorax treatment. In his opinion it is, indeed, the only method of treatment which gives any real chance of permanent benefit. Puncture is preferred to the open method advocated some years ago by Brauer. The various steps of the operation are described in detail; such complications as pleural effusion, air embolism, and pleural reflex are discussed, and the best methods of avoiding them pointed out. The comparative importance of air embolism and pleural reflex is not yet clearly defined, though, thanks to Brauer and his assistant Weber, the mechanism of gas embolism is now better understood. They have shown that it is not necessary to introduce air from without and through a hollow needle to cause air embolism; it may follow the wounding of a blood vessel, air from the lungs being sucked in through the opening. The belief that pleural reflex may be the cause of death following puncture of the chest has been disputed, but Dr. Burrell refers to two cases of his own in which the fatal issue may have been due to this cause; in one death was immediate. He classifies his first 150 cases into three groups. In the first an efficient pneumothorax was produced; in the second only a partial pneumothorax was obtained, treatment being continued for less than two months; and in the third pneumothorax was impossible owing to adhesion of the pleural surfaces. Among the 107 cases in the first group there were as many as 40 in which the disease was arrested and 22 in which improvement was effected. The results in the other two groups were not so good, and the difference in the results obtained in the first and third groups may be taken as the measure of the value of the treatment.

The second part of the Report consists of answers by sixteen British physicians to a set of questions addressed to them. These answers are published in full and are then analysed by the authors. It appears that since 1910 these sixteen physicians have dealt with between 14,000 and 15,000 cases treated by the production of artificial pneumothorax. The first and most striking fact is the unanimity of the replies—"... a favourable answer is returned by all with no uncertain voice." But some difference of opinion prevails as to the class of case most suitable for this treatment. On the one hand, Mr. H. Morriston Davies considers that no case is too early, and that an early case does not necessarily mean that the patient has a good resistance and will, therefore, respond satisfactorily to ordinary hygienic methods. Dr. Esther Carling, Dr. Lillingston, and others, on the other hand, would reserve this treatment for more advanced cases, and the general consensus of opinion seems to be that institutional treatment should, as a rule, be given a fair trial before collapse treatment is adopted. As the authors say, "however doubtful the operator feels of employing the method for an early case of tuberculosis, as soon as he perceives the disease is not yielding to ordinary methods of treatment an artificial pneumothorax should be induced as soon as possible."

The success of treatment by artificial pneumothorax has had remote as well as immediate effects. In addition to restoring many patients to comparative health, it has paved the way for other measures, such as thoracoplasty, which, without the lead given by pneumothorax treatment, would not have been so widely used. At the

¹ Report on Artificial Pneumothorax. By L. S. T. Burrell, M.A., M.D., M.R.C.P., and A. Salusbury MacNalty, M.A., M.D., Medical Research Council, Special Report Series No. 67. H.M. Stationery Office, 1922. (Pp. 164. 2s. 6d.)

For the assistance given by Dr. Clive Riviere, Vere Pearson, Dr. de Carse Woodcock, the late Dr. H. G. Jellison, Dr. R. C. A. C. Inman, Dr. Stanley Melville, and

meeting in April, 1922, of the Deutsche Gesellschaft für Chirurgie³ Brunner of Munich stated that Professor Sauerbruch had performed 500 thoracoplastic operations for pulmonary disease. His results and those of Professor Bull in Norway and Professor Saugman in Denmark are remarkably similar, and show that in about 30 to 40 per cent. of otherwise hopeless cases in the third stage of the disease the patient ceases to have sputum and becomes fit for work. In another respect treatment by the production of pneumothorax has influenced our conceptions of pulmonary tuberculosis. It has shown that the first essential to the arrest of active tuberculous disease in the lungs is immobilization, and that the more complete the rest given to a tuberculous lung the more rapid is the healing process. This principle is as old as it is sound, but a few years ago it was being challenged by the doctrine of auto-inoculation and of the focal reaction, which was a reversal of the adage, "Let sleeping dogs lie." Pneumothorax treatment has shown that immobilization, so successfully practised in surgical tuberculosis for many decades, is applicable also to pulmonary tuberculosis.

THE TREATMENT OF LEPROSY.

THE increasing use of the improved method of treating leprosy by intravenous and intramuscular injections of soluble products of chaulmoogra and other oils is already producing results undreamt of only a few years ago, as testified to by reports now arriving from affected countries in various parts of the world. Thus in India the treatment was commenced in the largest leper asylum in that country at Purlia early in 1921, under Dr. Muir's direction, and he has recently sent home the figures of the mortality among the 700 lepers there. These show a reduction of the death rate in the first six months to 66 per cent., in the second six months to 29.6 per cent., and the first six months of this year to only 21 per cent. of the average rates for the three years before the treatment was begun in the same months of the year—a remarkable result in a chronic disease in such a short time as eighteen months, even after allowing for some improvement in health due to simultaneous treatment for hookworms. Nor is this an isolated result, for recent reports received by the Mission to Lepers show a similar reduction of the annual death rate in the Fusan leper asylum from 25 per cent. to 5 per cent., the mortality in both this and the Purlia asylum having thus fallen to one-fifth of the former rate, while these and other similar institutions are now discharging a number of lepers apparently cured. What this means may be gathered from a recent report of Dr. Henry Fowler, Secretary for Eastern Asia of the Mission to Lepers, recording what he has actually seen of the effect of the treatment in Korea. He found there not less than 100 to 150 lepers who had lost nearly every trace of leprosy, and those previously crippled were now strong and able to engage in various occupations, including making bricks and tiles, and various manual labour, such as carpentering by the men, while the women were doing household work. He thinks that within ten years, with properly organized treatment, 75 per cent. will recover. The main difficulty is the cost of providing the drugs for the continuous treatment for many months of the large numbers of lepers who are now flocking to the asylums where the treatment has been successfully carried out. At Kwangju, for example, thousands of lepers are anxious for admission, and great efforts are being made to cope with this urgent problem. On the other hand, the success of the treatment in enabling previously helpless lepers to undertake regular labour once more is being taken advantage of wherever land belonging to the asylums is available for cultivation as at Purlia. This should make them more largely self-supporting, so that with the proper organization of leper colonies, as is now being done in Bengal, the very success of the treatment should help to set free funds formerly

spent on the maintenance of the helpless patients for the treatment of larger numbers. Another most encouraging feature is the number of comparatively early cases, in Hawaii and elsewhere, now coming forward voluntarily who formerly hid themselves as long as possible; this will go very far towards solving the hitherto immensely difficult problem of enforcing compulsory segregation among backward races, while the fact that so many of the treated cases become bacteriologically negative lessens materially the infectivity of the disease. Whether the new treatment ultimately proves to be a complete and permanent cure or not, it is already abundantly clear that it has opened up renewed hopes regarding the worldwide problem of the control of leprosy, and the great experiment of the treatment of 5,000 lepers at the Cullion settlement of the Philippines, recently inaugurated by Dr. Heiser, will be watched with much interest as a conclusive test on a large scale of the recent advances. The immensity of the problem, however, can hardly be overrated in view of the extensive tracts of Asia, Africa, and South America affected by leprosy. To deal with these, very special efforts will be necessary, including the arousing of public opinion to the necessity for liberal financial support, so that the outcast lepers may receive the advantages available for them.

THE SMYRNA FIRE AND THE SMYRNA HOSPITALS.

THERE seems to be no official information so far as to whether the British hospital at Smyrna is among the institutions that have gone down in the great fire. Probably this is not the case, as it was close to the Aidin railway station at the northern end of the town, and this is known to have escaped; moreover, the hospital lies in considerable grounds, surrounded by a high wall. It consists of three independent blocks—main, administrative, and isolation—all built of stone and each of two stories. But though probably not burnt it is only too likely that its contents have been stolen, for it lies on the edge of a "Maltese quarter" which is one of evil repute. Since the war, during which it was occupied by the Turkish authorities, it had not been fully reopened as an ordinary hospital, but one of the blocks was being used as a maternity home for members of the British colony, and it is said that at the time of the evacuation three recently confined women were inmates. The institution, but not the building, is of very old date. It was founded in the seventeenth century by the old Levant Company of British Merchants, which also provided it with maintenance funds by imposing a "hospital duty" on all ships consigned to the company. When the company dissolved in 1825 it stipulated for the continued maintenance of the hospital on the same lines, and this has always been done. It is thus perhaps the oldest example of a rate-supported hospital. The present buildings were erected just a quarter of a century ago, but, curiously, maps of Smyrna published last week by some of the newspapers show the British hospital still in its original position close to the British Consulate. After the rebuilding it continued to receive free all seamen from British ships, but also did a good deal of surgical work for paying patients of all nations. Part of the "French Hospital" (an institution of much the same kind) is known to have escaped, but the Dutch, Austrian, and Greek hospitals were all in the area definitely known to have been destroyed. The Austrian and Greek hospitals were both large, the latter having a number of insane wards attached. There was also more than one Turkish hospital, and a small institution of a missionary order known as the Scottish Hospital for Jews, but we do not know if the latter had restarted work since the war. It is common to speak of the Turks as if they were still mentally a mediaeval nation. This, however, can scarcely be the case if the information given us some twenty-two years ago by an English medical man, then lately returned from a long visit to Smyrna, was well founded. During his stay an outbreak of plague occurred which the local authorities, all Turks, had dealt with very promptly and with a success which was all the more remarkable as at that time plague was far less well understood in Europe than it is to-day. Among the measures they employed was the

³ Deutsche medizinische Wochenschrift, July 14th.

establishment of a bacteriological laboratory. All the workers therein were Turks, and the head of the laboratory, also a Turk, was described by our informant as one of the ablest young bacteriologists he had ever met, although he had received his education at the Turkish Medical School in Constantinople and had never been out of that city until sent to Smyrna.

THE MEDICAL SCHOOL OF MANCHESTER.

On Wednesday, October 4th, the University of Manchester celebrates the jubilee of the absorption of the Royal School of Medicine, a privately owned institution, with Owens College, which in 1880 became the first college of the now northern university under the name of Victoria University, and was later joined by Liverpool and Leeds. It was not until 1883 that the university was empowered to grant medical degrees, and now 90 per cent. of the students take the Manchester degrees. The Manchester medical school cannot be said to have begun with any well marked event, but from the foundation in 1752 of the Infirmary (of which Dr. E. M. Broekbank in his memoir of *The Honorary Medical Staff of the Manchester Infirmary. (1752-1830)* has given many interesting details) private instruction was given to medical students, especially by Charles White, one of the greatest ornaments of the Manchester school, as was shown in the published tributes paid to him by the late Dr. C. J. Collingworth and by Dr. J. G. Adams. In 1787 his son, Thomas White, also gave a course on the theory and practice of medicine, in the museum in his father's house. Peter Mark Rogot, the author of the ever-useful *Thesaurus of English Words and Phrases*, lectured in 1806, probably in the same museum; and John Atkinson Ransome's lectures on the principles and practice of surgery at a later date (1824) appear to have been the first provincial ones recognized by the College of Surgeons of England. These lectures were given in Thomas Turner's school of medicine, which, like Joseph Jordan's school of anatomy and some others, came into being early in the last century, and were succeeded by the Royal School of Medicine. After Owens College was founded in 1851 it was felt to be incomplete without a medical school, but it was only in 1872, after long negotiations, that the Royal School was absorbed. The University of Manchester is marking this jubilee anniversary by a reception to inspect the medical school and the recent extensions of the laboratories, and has issued an interesting fly-leaf, from which some of the historical details mentioned above have been taken. On the same afternoon the Manchester Medical Society is holding an open meeting in the physiological theatre of the medical school, when Sir Humphry Rolleston, K.C.B., President of the Royal College of Physicians, will give an address.

CREMATION IN ENGLAND.

THE modern practice of cremation as a substitute for earth burial owes much to the efforts of medical men. The revival of this hygienic method of disposal of the dead was urged in the middle of last century by many eminent European physicians and chemists, and in consequence a congress was held in 1874 at Milan. In this country the pioneer in the public advocacy of cremation was Sir Henry Thompson, F.R.C.S., but for many years prior to 1874 (as duly recorded in the *Encyclopædia Britannica*) Dr. Lord, Medical Officer of Health for Hampstead, had urged the practical necessity for the introduction of the system. In the beginning of that year steps were taken to found the Cremation Society of England. Among the leaders of the movement were Sir Henry Thompson, Sir T. Spencer Wells, and Mr. Ernest Hart, Editor of the *BRITISH MEDICAL JOURNAL*, the first-named being elected president and chairman of council on April 29th. In 1880 Sir Spencer Wells brought the matter before the Annual Meeting of the British Medical Association in Cambridge, and a petition to the Home Secretary for permission to adopt cremation was largely signed. This had no effect, and departmental obstruction continued; but

in 1884 a judge, Sir James Fitzjames Stephen, declared cremation to be a legal procedure, provided no nuisance were caused thereby to officials. In the following year the first cremation at Woking took place, and since then there have been upwards of 25,400 cremations in Great Britain. In 1893 the Home Secretary appointed a Select Committee of the House of Commons, presided over by Lord Ilkerton (then Sir Walter Foster, M.D.), and a leading member of the British Medical Association, to inquire into the efficacy of the existing law as to the disposal of the dead. The present practice is governed by the Cremation Act of 1902 and the regulations made thereunder by the Home Secretary. In its last annual report the Council of the Cremation Society of England records a gratifying increase in membership. An application for registration under the Companies Acts, sanctioned last year, has been submitted to the Board of Trade, which has approved the necessary Memorandum and Articles of Association. The Society continues to receive prominent medical support; among its Vice-Presidents are Sir Anderson Critchett, Sir Frederick Treves, and Sir John Tweedy (honorary treasurer), and the Council includes Sir Malcolm Morris and Dr. H. T. Herring. Nevertheless, progress is still very slow. At the present time less than 2,000 bodies are cremated annually in these islands; all the rest (some six or seven hundred thousand) are buried in the earth, and "every year the silent population of Greater London is increased by another hundred thousand."

THE HONG-KONG CHAIR OF MEDICINE.

IN our advertisement column there appears this week a brief statement of the conditions attached to the newly created Chair of Medicine at Hong-Kong University, and prospective candidates may welcome some further information that has been supplied to us unofficially with regard to this appointment. The University of Hong-Kong was established in 1912 upon the initiative of the Governor of the Colony, Sir Frederick Lugard, and in 1921 received further endowment from the Colonial Government which has placed it on a secure financial basis. The university is for the education of Chinese students in European knowledge; its faculties are those of medicine, engineering, and arts. Wealthy Chinese have given generously towards its buildings and establishment, and British commercial firms in China have also made large contributions. The university has absorbed the old medical school that owed its origin in 1887 to the energy of Sir Patrick Manson, who laid the foundations of his great reputation in tropical medicine by work in Formosa and Hong-Kong. The Prince of Wales, during his recent tour in the East, was made an honorary L.D. of the university, and on that occasion (April 7th, 1922) it was announced that the Rockefeller Foundation in America had resolved to give half a million Hong-Kong dollars (approximately £60,000) to the university for the creation of a modern school of medicine with professors in medicine and surgery who should devote their powers to teaching and research. A further donation of a quarter of a million dollars is in prospect for a chair of obstetrics when the school is ripe for this extension. Training for research into disease is plainly one of the aims which must be fostered by this Hong-Kong school of medicine. The great opportunities of the school were finely expressed by Sir Patrick Manson in his inaugural address as dean of the old college in 1887: "I can conceive of no grander position or opportunity for any man to have than that we offer here. At his back the whole of European science; before him 300,000,000 to whom to give it. Such a position must fire the ambition of anyone." The chair of physiology has been held for some time by Professor H. G. Earle, of Cambridge University, and that of pathology by Professor C. Y. Wang, M.R.C.P., who was educated at Edinburgh University and held a Carnegie Research Fellowship. The Rockefeller gift has enabled anatomy to be separated from surgery; the latter chair will

be continued by Professor Kenelm H. Digby, of Guy's Hospital, and anatomy will be taught by Professor J. Shellshear, D.S.O., of Sydney, Australia. In the appointment to the chair of medicine preference will be given to candidates not older than 35, and ability for teaching and research will be expected. A senior resident assistant and a resident house-officer are attached to the post. The election has been entrusted to a Committee at the Board of Education, Whitehall, which includes two of the recently appointed whole-time professors of medicine in the University of London. The salary is £300 a year, rising to £1,000, payable while the professor is in the colony at the rate of 2s. to the dollar (and in addition the university pays part of the insurance premium to the Universities Superannuation Fund). The salary may be supplemented by fees for consultations in the colony, but the expectation is that the professor will devote himself chiefly to the work of the school. There is no income tax in Hong Kong, and local rates and taxes are almost negligible.

LIFE TABLES.

THE current issue of the *Journal of the Royal Statistical Society* contains the report of a discussion on the "Value of life tables in statistical Research," opened by Dr. Major Greenwood, and continued by several eminent medical statisticians and actuaries.¹ Medical officers of health who have regarded with envy those of their colleagues who could and did construct life tables will perhaps draw some comfort from the discussion, because most of the speakers were at no pains to disguise their opinions that nothing more could be learned from a life table, so far as the sanitarian was concerned, than from the death rates at ages. In the view of Mr. A. Henry, the Deputy Government Actuary, the great objection to the construction of life tables was that it allowed people to talk of "that quaintly designated thing, the expectation of life." It was, he said, a horrible term. It had no practical meaning, and it had caused more trouble in the minds of laymen, he thought, than almost any other actuarial function. He took it that the real reason for such measures as the life-table death rate and a standardized death rate was that people were not content to do the simple work of comparing the rates of mortality age by age. They wanted something in the nature of a composite picture of the whole table. They had variations in rates of mortality from the infantile to the oldest ages. They had variations in mortality which might go in opposite directions and react one against the other; and he suggested that Dr. Greenwood was perfectly right in saying that the only true comparison was a comparison either age by age, or, which he thought personally was more preferable, over short periods of the table, using the probability of living five to ten years, which might eliminate accidental errors. To a question of the opener, "What available information could be deduced from mortality data expressed in life-table form which was not afforded by the central death rates themselves?" Mr. Palin Elderton answered, "None." He was quite clear about that. His difficulty, he said, had always been this: he could not see why people could not be content with examining rates of mortality and comparing those rates between two tables and leaving it there. Dr. W. H. Hauser made a contribution to the debate which, even if its relevance to the subject be doubtful, is worthy of transference to our columns on its intrinsic merits. The evolution of the relationship of the statistician to the public health official was, he thought, very well illustrated in La Fontaine's fable of the miller, his son, and the ass: "The miller, of course, is the statistician, the son is the laboratory worker applying statistical methods, and the ass, as before, is the Medical Officer of Health. In the Victorian age, which, be it remembered, was an idealistic age, the miller and his son were so careful of the ass that they bore its weight upon a pole, which they carried on their shoulders;

then certain critics said it must be set on its feet; then again, in order to silence further criticism, and yet more criticism, first the son, and after that the miller, mounted upon the ass's back; then there was more trouble, for a fourth set of critics considered that the ass's life should be spared, and the miller and his son accordingly dismounted. The miller seemed more or less to acquiesce in this last arrangement. At all events, he was convinced that there had been too many changes, and he seemed to think that he, his son, and the ass had better settle down to business and get on with their journey. The moral of all this seems to be that each man must do his best, and no one, as La Fontaine says, can escape being criticized, whatever he does! 'Les gens en parleront, n'en doutez nullement.'

PSORIATIC ARTHROPATHY.

OUR new contemporary, *Acta Radiologica*, representing the activities of medical radiology in Denmark, Finland, Norway, and Sweden, and containing articles in English, French, and German, is admirably got up and illustrated. In the first number there is an interesting record of a case of psoriatic arthropathy with excellent skiagrams of the hands and feet, which are specially welcome, as the only others that the author, Dr. S. Ström of Stockholm, can refer to are those in a paper on the various forms of ankylosis by Ledoux-Lebard. The predominating change is bony destruction, often extending beyond the joints so as to leave small fragments only of some of the phalanges, while the other phalanges show atrophy. The hypertrophic changes described by French observers were insignificant. The skiagraphic appearances are said to resemble those in Raynaud's syndrome, scleroderma, syringomyelia, and nerve leprosy, and therefore support the view that psoriasis has a nervous origin. Dr. Ström does not find any evidence in favour of Brock's hypothesis, based on improvement after the administration of stimulating doses of x rays to the thymus, that disordered internal secretion is responsible for psoriasis. Though very rare, the arthritic lesions in patients with psoriasis have attracted a considerable amount of interest, largely from their bearing on the nervous hypothesis of this common skin eruption. They are usually multiple, chronic, without any liability to cardiac complications, uninfluenced by salicylates, prone to attack the hands and wrists and to cause ankylosis, and have generally been regarded as belonging to the group of nervous arthropathies, a view now supported by Ström's radiograms.

THE VISCERAL CONTENT OF ARSENIC.

THERE is a general impression that arsenic when introduced into the body specially picks out certain organs—the liver and the spleen—and in 1919 Sicard explained the jaundice after treatment with salvarsan as toxic and dependent on a special affinity of arsenic for the liver. This belief, current long before Ehrlich's terminology came into vogue, may perhaps be regarded as an intelligent anticipation of his organotropy or special affinity of a drug for some one organ or tissue. Milian,² in a recent review of the available data on the quantitative distribution of arsenic in the viscera, combats the conception of any such selective localization; there is, he observes, a normal content of arsenic in the viscera which does not correspond with that found when arsenic is artificially introduced into the body. He argues that the visceral content of arsenic varies with the route by which it gains entrance to the body. Thus when the drug is taken by the mouth the maximum amount is found in the liver; but after intravenous injection of the arsenobenzol compounds the lungs and spleen show the highest arsenic content; an observation by Jeanselmé makes it probable, he thinks, that the same holds true in the case of intramuscular injections of the arsenobenzol compounds.

COD-LIVER OIL AND VITAMIN A.

RECENT INVESTIGATIONS.

A series of papers has appeared this year which gives a large amount of interesting information concerning the source of the vitamin present in the cod's liver and the effect of processes of extraction upon this vitamin.

Experiments upon land animals have shown that these cannot synthesize vitamin A, and obtain their necessary supplies of vitamin from chlorophyll-containing plants, either directly, by eating green vegetable matter, or indirectly, by eating the milk or flesh of other animals. The investigations described below show that a similar process occurs in the sea and that the whole of the vitamin A required to support life in the sea apparently is synthesized by plants containing photocatalytic pigments. A peculiarity of the vitamin A exchange in the sea is that the main source of vitamins for deep-sea animals are the micellular algae, and the vitamin is transferred through a series of animals of ascending size before it reaches large fish, such as the cod.

Jameson, Drummond, and Coward¹ showed that a marine diatom (*Nitzschia closterium*) grown in a sterile culture fluid synthesized large quantities of vitamin A. The research was interrupted by the sudden and untimely death of Dr. Jameson, but Drummond, Zilva, and Coward² traced the vitamin exchange farther, and showed that the plankton fauna, which lived on the diatoms, contained large amounts of vitamin A. This plankton, which consists largely of copepods and larval molluscs, is the source of the vitamin A which is found in large quantities in the livers of all fishes. The plankton forms the chief diet of a large number of marine animals, varying in size from minute fishes to whales; the cod, however, lives chiefly on small fishes; in the case of the cod, therefore, vitamin A is formed in diatoms and passes through two intermediate carriers—namely, the plankton and small fishes—before it reaches the cod.

A remarkable and very important point about the marine vitamin exchange is that the concentrations of vitamin A attained are much higher than occur on land. The following table shows the source of vitamin A and the approximate weight of substance in grams required to produce growth in rats weighing 100 grams:

Source.	Approximate Weight.
<i>Marine sources:</i>	Gram.
Diatom (<i>Nitzschia closterium</i>) (dry weight) ...	0.04
Plankton (dry weight) ...	0.1
Small fish (capelin, <i>Mallotus villosus</i>) ...	0.1
Cod-liver oil ...	0.003-0.01
Cod's roe (male) ...	0.025
<i>Land sources:</i>	
Green vegetables (cabbage) (dry weight) ...	0.1
Butter ...	0.1-0.2
Ox liver ...	0.25

The Manufacture of Cod-liver Oil.

Cod-liver oil was originally produced by the simple method of putting the livers into a tub, leaving them to putrefy, and skimming off the oil. This method produced an oil of rich golden brown colour, with a strong and objectionable taste and smell. Möller, in 1853, introduced the method of extraction by steam, and practically all the oil is now produced by this method. The oil thus produced is nearly colourless and has no smell, and only a slight taste.

There is a widespread belief that the modern oil is a less efficacious therapeutic agent than the old brown oil, and when the therapeutic action of cod-liver oil began to be associated with its high vitamin content it was suggested that possibly the modern methods of manufacture tended to destroy the vitamin. This question has been investigated by Drummond and Zilva,³ who found that there was no evidence that the "steaming" method of production of cod-liver oil destroyed the vitamin A in the oil. Investigation in Norway showed that the cods' livers were removed from the freshly killed fish and were placed at once in vats, and the oil separated by low pressure steam (direct or indirect). The first fractions of the oil obtained, which are the only ones used for medicinal purposes, are nearly colourless, and the

chief further refinement to which they are subjected is freezing to remove stearine. The latter fractions of the oil recovered by the "steaming" process are coloured, and a small amount of brown oil is still obtained by the "rotting" process. The authors conclude, however—

"After personal investigation of many factories, and careful interrogation of many sources of information, we came to the conclusion that very small and quite negligible quantities of crude 'brown' oils are refined to produce medicinal oils. Several processes for this refining have at one time or another been put forward in patents, but as far as we are aware none has proved of any commercial value on a large scale."

Experiments also were made to compare the vitamin content of the crude brown oils, of the colourless oils, and of oils prepared in the laboratory; in the last case every precaution was taken to prevent any destruction of the vitamin. From these experiments the authors conclude:

"From our exhaustive investigations of the effect of the modern processes of the preparation of cod-liver oil on its vitamin value we have formed the opinion that the 'steaming' methods yield oils of as high, if not actually higher, potency than were yielded by the old and almost extinct 'rotting' process."

"Further, the modern methods of refining, if we exclude, as we justly may, the almost negligible amount of bleaching of dark oils which occurs, scarcely affect the vitamin value at all."

"In the light of these observations it is obvious either that the popular belief that the 'dark' oils are more valuable as medicinal products than the modern 'white' oils is erroneous or that such beliefs arose at a time when some actual difference existed."

Sixteenfold variations may occur in the vitamin content of different samples of cod-liver oil, although even the least active samples of cod-liver oil contain more vitamin than does butter. Drummond and Zilva believe that these variations are a reflection of changes in the diet or in the physiological state of the fish at different seasons. The authors further note that the livers of other fish yield an oil as rich in vitamin A as cod-liver oil, and that therefore there is no obvious reason why the livers of other fish than the cod should not be used for medicinal purposes. They further question the utility of removing the stearine from cod-liver oil, as this substance is rich in vitamin A.

Tests for Vitamins.

The investigation of vitamins is, of course, greatly hampered by the fact that the only tests available for demonstrating their presence or absence are biological tests, which are difficult, expensive, and extremely tedious. A chemical test for vitamins would be of the greatest possible value, and it is interesting to note that Drummond and Watson have discovered indications of the possibility of such a test for the vitamin A present in cod-liver oil. Cod-liver oil dissolved in chloroform or carbon bisulphide and shaken with a drop of sulphuric acid gives a violet-red coloration, and this is one of the old pharmacopoeial tests (U.S.P.) for cod-liver oil.

Drummond and Watson⁴ examined a series of fish oils and found that their vitamin content varied about tenfold, and that the intensity of the colour reaction also varied greatly, and they showed that the variations in the vitamin content and in the intensity of the colour reaction were roughly parallel. They also showed that the passage of air through cod-liver oil at 100° C. slowly destroyed the vitamin A present, and that the colour reaction was abolished by the same process, and that the vitamin and the chromogenic substance disappeared at the same rate. They conclude that—

"The few properties of the (chromogenic) substance which are known, as well as the available data regarding its distribution in the various tissues, show certain points of similarity to the unidentified substance which is the vitamin A. It is, therefore, of some significance."

There is no doubt that the work reviewed in this article greatly increases our knowledge of the vitamin A in cod-liver oil. The definite evidence as to the origin of the vitamin and the way in which the vitamin is passed through different classes of the marine fauna until it finally reaches the cod reveals an aspect of deep-sea metabolism which is of great interest. The evidence as to the influence of manufacturing processes upon the vitamin in cod-liver oil is most important, and also rather unexpected. Finally, the suggestion that it may be possible to find a chemical quantitative test for vitamin A is of the greatest importance, for such a test would facilitate enormously the investigation of vitamins.

THE MANSON MEMORIAL MEDAL.

PRESENTATION TO LADY MANSON.

THE presentation to Lady Manson of the first medal struck in memory of the late Sir Patrick Manson took place at the London School of Tropical Medicine on September 26th.

Major-General Sir WILLIAM B. LEISHMAN, F.R.S., addressing a small company, which included several of Sir Patrick's most distinguished associates, gave a brief history of the Manson Memorial Fund, the proceeds of which, in part, have gone to the issue of the medal. He said that it was the feeling of many of those connected with the School that a worthy portrait of Sir Patrick Manson should be secured for its walls. Nothing in the nature of public appeal was made, but in response to letters to Manson's old friends and fellow-workers subscriptions came in from all parts of the world, and the letters accompanying the subscriptions were remarkable alike for the eminence of some of the writers and for the personal tributes which they contained. As a result of this private and narrow appeal about £300 was collected in a very short time, an amount considerably greater than was necessary to secure the portrait in question and to have mezzotint reproductions of it made for presentation to all the subscribers. The committee of the fund, of which the speaker was chairman, decided that the balance should be devoted to the striking of a medal, to be known as the Manson Memorial Medal, and to be presented triennially to any workers who gained special distinction in tropical medicine. It was a graceful thought on the part of the governing body of the School that the first medal should be presented to Lady Manson. This presentation was not meant as a mere empty compliment. The governing body felt that the first medal would properly be given to a lady who had personally done a great deal to further the cause of tropical medicine. In more than one way could a wife help her husband in his work. Some wives were able to assist in the direct way, as, for instance, by association in laboratory research; but there was an indirect way at least as important and helpful as the other. As a man most fortunately married himself, he (Sir W. Leishman) knew in how many directions a man's work could be helped by his wife, merely by the creation of a

sympathetic atmosphere, perhaps by a little word of flattery when others outside were engaged in criticism, and especially by encouragement in times of difficulty or failure such as came to every research worker. In these respects the stimulus given to a man by his wife was very real indeed, and in all of them Lady Manson had shown her devoted skill, so that her contribution to the science which made her husband famous was nothing small.

Sir William Leishman then handed the medal to Lady Manson with the warmest congratulations and good wishes of the School.

Dr. P. H. MANSON-BAHR said that Lady Manson had asked him, her son-in-law, to reply on her behalf. She wished to

thank Sir William Leishman and the School from the bottom of her heart. This was one of the greatest compliments which could have been paid her. The medal would be among her most treasured possessions and an heirloom in her family. She was especially gratified, because this medal was also commemorative of the London School of Tropical Medicine, which Sir Patrick Manson, their revered master, did so much to create, and the welfare of which was uppermost in his mind to the very last day of his life.

The medal presented to Lady Manson is in bronze, and (as our reproduction indicates) it bears on its obverse a very fine portrait in relief, doing justice to the rugged face. On the reverse are the words "London School of Tropical Medicine." The medal, which

is to be presented to distinguished workers in this subject, will bear on the reverse a device embodying "Tropical Medicine and Hygiene," in recognition of the fact that the recipients will be selected by the Council of the Royal Society of Tropical Medicine and Hygiene. The medal is the work of Mr. J. R. Pinches, of Albert Embankment, London, who was fortunate enough to obtain a special sitting for his purpose only a few days before Sir Patrick Manson's death. The medal, therefore, which was greatly admired, is a more sympathetic interpretation of the man than is usual with medallion designs which are reconstructed from photographs. A large oak-framed plaque in bronze, bearing the same design, is placed in the library of the School. It was from this large model that the photograph we reproduce was obtained.

Nova et Vetera.

HONORARY GRADUATION IN THE OLDEN TIME.

THE seventh centenary of the foundation of the University of Padua was celebrated last May with becoming pomp and ceremony. Ambassadors of science from the ends of the earth graced the high festival, and these in turn were honoured by the laureation of some of the most distinguished among them. Such ceremonial degrees are, however, no novelty to us of the present day, and to most their bestowal at Padua would not give rise to a second thought. In the minds of those who fetch their precepts from the Cynic tab there may indeed have risen a doubt as to how far time would set the seal of its ultimate approval upon Padua's choice. From the past we may at least glean some suggestions towards an answer. Three chance samples from the Cinquecento may not afford a broad enough basis for a generalization, but, in any event, the details are not without an interest of their own.

In the beginning of October, 1515, Pavia welcomed a band of strangers from across the Alps. No peaceful pilgrimage this, but a roystering array of French knights, their swords still reeking with Italian blood. Some days before, Francis I had won the sanguinary battle of Marignano against the

Milanese, and therefore did Pavia mightily rejoice. Every citizen vied with his neighbour in doing honour to their liberators, and the university was anxious to play its part. It so happened that among the suite of the Duke of Lorraine was his surgeon, Symphorien Champier, by name, a graduate of Montpellier, who, after a distinguished career as a practitioner and town councillor at Lyons, had donned a coat of mail and emulated the feats of his wife's cousin, Bayard. So valiantly had he acquitted himself in this capacity that the golden spurs of knighthood were granted him by the duke on the field of battle at the very moment that Francis I received from Bayard a similar honour. But, though his patent was but a fortnight old, Champier had seen forty-four summers, and the harvest of his intellectual activity was already represented by seventeen printed volumes—a veritable encyclopædia in black-letter. To him, therefore, the university resolved to give an honorary degree, and to his indefatigable pen we are indebted for a record of the proceedings.

"Patres optimi," began the dean, Rusticus, of Placentia, "rejoice, yea, rejoice again and again, and be glad, ye, whose names are written abroad through the world! Rejoice and be glad in the first place, that after the fears and agitations of these many years had forged a chain of death about us there has come amongst us the most invincible and most Christian Francis, King of the French and our own Duke. He shall wipe away every tear from our eyes, nor shall there

any more grief or lamentation or sorrow. The sun of alienation shall no longer burn us up, and all things shall be new. Rejoice in the second place, and be glad, because uphonor Champier is about to enter our ranks, a man, one of the learned most learned, among the most learned, excellent, and among the most excellent most eminent. So in family and fatherland, he is still more noble in his own, and most noble of all in his learning."

He need not follow the orator through the rest of his eel, which is pitched in the same key. The final invitation, the grand runs thus: "Come, then, O effulgent gem of France, O priceless pearl, whose wife is a pearl of beauty!" (Her name was Margarita.) "Come, father and brother, and go to accept the highest honour we can bestow, although acceptance is a greater privilege to us than to you. We say that your days may be happy and that you may always remember the learned men of this college, who for their part will never forget you."

The next ceremonial we will relate occurred in the same hall a few days later, and again Champier gives us the tails, *quorum pars magna fuit*. Among the French nobles Pavia was the brother of Mousigneur de Lorraine—nely, the Duke of Guise, first of that line, and destined to be the grandfather of Mary, Queen of Scots. He had in his day a barber-surgeon, a Picard called Hyppolite Daultreppe, who eagerly desired academic distinction. Accordingly he sought Champier to persuade the Faculty to grant him the degree of Doctor of Surgery. Champier's new friends at once acceded to his request and no less than twenty-two appeared to lend dignity to the proceedings. At the outset, however, a very serious difficulty arose when it was learned that Daultreppe had no Latin, and that even "French of Paris was to him unknown." The Professor of Medicine issued the universal indignation. "We are astounded, excessive Champier," cried he, "that you have asked us to assemble here, as we have done in such large number, to grant a degree to a man who is destitute of knowledge and is not even a smattering of Latin. We can only assume that he wanted to trick us or make us look foolish." But Champier was equal to the occasion. "Brother and Menege," he replied, "tell me this: if Galen and Avicenna were alive to-day, and came to you and asked for a degree, would you grant it them?" The answer was, "Certainly! such men could not be refused." "Note this, then," continued Champier, "that neither knew Latin, though both were most distinguished physicians. particular language is, therefore, not an essential to knowledge, since this can be acquired through the medium of other tongues, even through Arabic which we regard as barbaric." He then went on to argue that the real test in his case was the surgical attainments of Daultreppe, and these they could ascertain at once by using him as interpreter. The disconcerted assembly at length accepted the offer and the interrogation began. Champier translated the questions to Daultreppe, and then rendered his answers into Latin. All difficulties were surmounted with such consummate ease by the candidate that the doctors were astonished into silence. It is clear that they were not without suspicion that most if not all the learning displayed in the answers came from the stores of the interpreter. This, however, was too delicate a matter for them to probe, and so the Picard got his degree.

Like Daultreppe, the third subject for consideration was Frenchman, who as a barber-surgeon had accompanied an army into Italy. He too had given distinguished service to Guise—Francis, the second duke—snatching him from the clasp which was later to reach him by an assassin's hand. In his case Pavia would not have been so sore distraught, for he lacked Latin he knew Italian fairly well. Him in 1554 the French King desired to honour with a degree. It would appear from the subsequent open enmity of the medical faculty against the man that with them the King's wish was of no avail. Fortunately the College of St. Cosmas was complaisant; but here again the difficulty in regard to Latin arose. At length by special vote the rule was for once suspended, and the candidate passed through the successive grades of Bachelor, Licentiate, and Master of Surgery at intervals of only two months.

Now what is the verdict of posterity on these three men? Of Champier's final reckoning of fifty volumes the rare copies are still extant. "at peace remain, Amid their kindred cobwebs in Duck Lane." Daultreppe swims into our ken with that scene at Pavia, but

of him no more. Of the last it is only necessary to mention that his name was Ambroise Paré.

But we must not judge the past too harshly or expect too much from the present. Like other human institutions, universities are liable to err in their choice as in their rejections. But corporations have no souls. This is fortunate for universities, since all of them have much to regret.

G. M. C.

England and Wales.

OPENING OF THE NEW SESSION IN LONDON.

Next week will see the opening of the new winter session at the London medical schools. At St. Bartholomew's Hospital Medical College the occasion will be marked by the holding of the annual old students' dinner at the Hotel Victoria on the evening of October 2nd. At Charing Cross Hospital Medical School the prizes will be distributed on October 3rd at 3.30 p.m. by Viscount Burnham, and the annual dinner will be held that evening at Oddens's Imperial Restaurant, Regent Street. Sir Clifford Albatt will give the inaugural address at St. George's Hospital Medical School on October 2nd at 3 p.m. At Guy's Hospital Medical School there will be no formal ceremony on October 2nd, but the new anatomy and biology buildings will probably be completed during this session, and will be opened next summer. At King's College Hospital Medical School the introductory address will be given by Sir Horbert Jackson on the afternoon of October 3rd, and the annual dinner of past and present students will take place that evening at the Café Royal, Regent Street. The introductory address at the Middlesex Hospital Medical School will be given at 3 p.m. on October 3rd by Professor Sidney Russ, the prizes will be distributed by H.R.H. Princess Alice, Countess of Athlone, and the annual dinner will be held that evening at the Trocadero Restaurant. At Westminster Hospital School of Medicine Mr. G. T. Mallally will give the introductory address on October 2nd at 3 p.m., and the annual dinner will be held in the evening at the Wharfedale Rooms. The annual dinner of past and present students of St. Mary's Hospital Medical School will take place at the Connaught Rooms on October 2nd at 7.30 p.m. The session at St. Thomas's Hospital Medical School begins on October 3rd, and the old students' dinner will take place at Princes' Restaurant on November 10th, with Sir Charles Sherrington, President of the Royal Society, in the chair. Viscount Burnham will give the introductory address at the London (Royal Free Hospital) School of Medicine for Women on October 2nd at 3 p.m.

MILK PROSECUTIONS.

We have received the following statement from the Public Information Branch of the Ministry of Health:

Health Ministry and Milk Prosecutions.

"The following statement is a number of quarters to misrepresent months ago by the Ministry of Health, to forbear in certain clearly defined prosecution of milk vendors. The Circular is rarely quoted as a whole, and in view of the fact that sentences torn from their context have been used to suggest falsely that the Ministry is tolerant of laxity in the production of milk it becomes desirable to restate what the Circular does and does not advise.

"It is based upon an actual case of unsuccessful prosecution by a local authority of a milk vendor who was charged with selling milk deficient in fat. In the Court it was shown that the vendor had held a good record for a number of years, and that repeated tests of his milk during that time had given uniformly satisfactory results; also, that 'special circumstances existed to account for the prosecution being based.' It was stated that the local authority had made no attempt before prosecuting to ascertain why on this isolated occasion the milk had failed to pass the test, and that the vendor had not volunteered the necessary information. But when the facts were revealed in Court the local authority at once withdrew the prosecution.

"The advice given in the Circular is expressly limited to cases in which the circumstances are similar to those described. It states that 'the Minister is of opinion that it is extremely undesirable that a prosecution should be based upon the results of an isolated test when other tests of the particular milk supply have shown it to be satisfactory'; and it suggests that 'in such cases prosecution should be instituted only where a series of tests have shown a repeated default.' It is therefore incorrect to represent that the Circular has any general application. The only cases in which it deprecates the institution of a prosecution 'based upon the results of an isolated test' are those in which a milk vendor has held

a consistently good record for a number of years during which his milk has been constantly tested with uniformly satisfactory results."

Readers who turn to the article in our issue of August 5th (p. 232) on milk prosecutions, and to the paragraph with the same title, on August 19th (p. 325) referring to the action taken by the Society of Medical Officers of Health, will be in a position to judge the value of the defence now put forward by the Ministry of Health.

RED CROSS ACTIVITIES IN LONDON.

The annual report of the County of London Branch of the British Red Cross Society shows that, although the activities of the Society are less obvious in times of peace than in war, they are being directed into channels of considerable value to the community. The Red Cross clinics which have been organized in London have attained a high degree of success; the work of the clinics has assumed dimensions far greater than was anticipated, and the gratitude of the men who have been treated at them is a testimony to their value. At the end of last year ten clinics were open in the County of London, and five of them had tropical disease branches; in 1921 there were 142,831 treatments given in excess of those of the previous year, and the total treatments since the clinics opened amount now to considerably over half a million. Besides work at the clinics and Red Cross institutions, at all of which members of the Society are giving voluntary assistance, members have worked in various capacities in several civil hospitals and other institutions for the sick and disabled. As an example, the Camberwell Division during 1921 did very useful work in connexion with King's College Hospital; a scheme was initiated after the war by which members of the detachments helped the hospital by visiting homes of in-patients prior to their return, and explaining what arrangements were necessary for them, by visiting discharged in-patients and casually patients after treatment in the hospital; doing clerical work at the hospital, making and mending garments, etc. The Division has also recently entered upon another sphere of usefulness in connexion with the Hostel for Crippled Working Girls, Denmark Hill; many of the girls in this institution have to pay regular visits to various hospitals for treatment, and they are escorted to them by members of the Division. At Greenwich and Woolwich Red Cross members work at local welfare centres, and assist district nurses; several members of the Marylebone Division are still working in hospitals in the evenings and week-ends, and similar voluntary work is carried out by members of other divisions in London. The Westminster School Treatment Centre may be given as another instance of the work of the society. This is the first of its kind opened in London; it is organized under the auspices of the Westminster Division for the treatment of minor ailments among children attending elementary schools; there has been an average weekly attendance of 147 children, the now cases averaging 14 a week. The medical supply depot established by the Camberwell Division has been found to be so useful that other depôts were established in various parts of London for the benefit of poor persons, with the aid of grants by the executive committee of the Branch. From these examples it will be gathered that Red Cross work in London is still very much alive, and there are many members who give a very large measure of their time and services to keeping the work going.

Scotland.

THE VITAL STATISTICS OF SCOTLAND FOR 1922.

The Scottish Registrar-General's Report for 1922 has been mentioned in the JOURNAL of July 23rd (p. 176), and again on August 26th (p. 399). We now give a fuller account of its contents. The population of Scotland in the middle of 1920 is estimated at 4,864,396, the estimate being safely based on the census of 1921.

Births.

The births numbered 136,546, the maximum since registration began; they were 30,278 in excess of the previous year, and 22,592 more than the mean of the previous ten years. The rate was 28.07 per 1,000, or 4.17 above the average of the previous ten years and higher than any year since 1908. The rise began in September, 1919, and reached its maximum of 32.2 in March, 1920, then gradually subsided to 25 in

September. Illegitimate births to the number of 10,204 were registered, a larger number than in any year since 1887; the rate was 7.47 per 100 births, very slightly above the mean of the preceding ten years.

Marriage and Divorce.

The marriages registered were 46,843, also a record, being 2,783 more than in 1919, 11,511 more than the mean of the previous five years, and 12,781 more than the mean of the ten preceding years. Also they are 13,167 more than the maximum in any year previous to the war. The rate, 9.63 per 1,000 of population, was likewise a record, being 1.86 more than 1873, the pre-war record holder.

In the number of divorces there has been an astonishing increase. The total in the year was 776, or one to 60 marriages. Fifty years ago (in 1873) the ratio was one in 1,403. The minimum was in 1864, when there were only two divorces, and 1865 and 1866 had only four each. The figures have never fallen below 100 since 1890; in 1918 they reached 485, in 1919 829; and in 1920, as already stated, 776. These last two years between them have had more divorces than the thirty-seven years 1855 to 1891 inclusive.

Deaths.

Deaths registered numbered 63,179, or 5,645 less than the mean of the previous ten years, and yielded a rate of 14.02, the lowest yet recorded for Scotland, the previous lowest having been 14.45 in 1917.

The infantile mortality rate was 92 per 1,000 registered births, also a minimum for Scotland, and 15.9 less than the mean of the ten preceding years, the previous minimum having been 97.1 in 1916. In the last five years an infantile mortality rate of less than 100 has been recorded three times. Previous to 1916 it was constantly over 100, and only exceptionally under 110. At the other extreme of life the ages of nine reputed centenarians were verified, and in the course of eleven years 59 such verifications have been made. Among causes of death small-pox and cancer were unusually prevalent, the former being registered in 152 cases, or more than in any year since 1904. Deaths from cancer have had a new maximum in 1920, the number being 5,765 and the rate 119 per 100,000 population; fifty years ago it was 43. On the other side of the account we find that the phthisis rate fifty years ago was 283 and is now only 85. In fact, phthisis and all forms of tuberculous disease, likewise whooping-cough, reached their lowest recorded death rate in Scotland in 1920, whilst the measles rate was lower only in three previous years—namely, in 1879, 1886, and 1894. Similarly the diphtheria death rate of 1920 was less than in any previous years excepting 1903, 1905, and 1917. The death rates from all tuberculous diseases were less than a third of what they were fifty years ago.

Vaccination.

As to vaccination, of the children born in 1919 and reaching the statutory vaccination age only 58 per cent. were reported successfully vaccinated. That is somewhat better than in the previous year, but prior to 1907 (the year of the last relaxation of the law of vaccination in Scotland) the rate was constantly over 90, and often over 95 per cent.

Additional Details.

The above figures are taken mainly from a condensed general account with which the Registrar-General conveniently begins his Report. He then proceeds to fuller detail from which some further notes may be made.

Births.—The ratio of male to female children was 104.3 to 100. In the counties including burghs the birth rate varied from 32.3 in Linlithgow and 31.9 in Lanark to 16.8 in Argyll and 17.3 in Bute. In the group of "larger burghs" (with 30,000 inhabitants or more) the birth rate was 30.18 per 1,000, in the smaller burghs (under 30,000) 27.37, and in the county districts 25.52. The highest rate in the larger burghs was in Hamilton, 34.1, and the lowest in Perth, 24.1. In the smaller burghs the rates varied much more—from 43.3 in Rothes to 9.8 in Melrose, but of course in small populations there is more room for chance variation owing to paucity of data. In county districts the highest rate was 34.4 in the Middle Ward of Lanarkshire, and the lowest 10.3 in the Cowal District of Argyllshire. Calculated on the number of women of child-bearing age, the birth rate per 1,000 of such women was 116.6, or 25.4 more than in 1919, 32.8 more than in 1918, and 33.2 more than in 1917. In the larger burghs the rate ranged from 165 in Coatbridge to 88 in Edinburgh.

Illegitimacy has diminished with passing years. During the period 1852-57 the numbers annually were always over 10,000, then up till 1919 they were always under 10,000, and the minimum (7,295) was reached in 1917. The illegitimate rate as a percentage of the total birth rate differed remarkably as between one area and another. The county districts are higher (8.64) than the

larger burghs (6.99) and the smaller burghs (6.94). In certain counties—Moray, Banff, Aberdeen, and Caithness in the north and Wigton in the south—the illegitimacy rates are very low. Whether the figures represent a corresponding difference in morality is another question. Of the total children born in Scotland 2.67 per cent. were twins (3,644 children) and 0.03 per cent. (45 children) were triplets. A table of monthly birth rates is given for the years 1914-20, showing the influence of the war. The rate, which, as it happened, had been rather high in the winter of 1914-15, began to fall below the pre-war average from about the middle of 1915, and continued so right on until October, 1919. It rose to a maximum in the winter 1919-20, then declined again, though not quite falling so low as the pre-war average of 1920.

Marriages.—In the counties the rates varied from 12 per 1,000 of population to 4.1 in Argyllshire. A table is given to show the monthly marriage rates as influenced by the war, from August, 1914, till the end of 1920. Up to the end of 1917 the rates were very irregular, 22 months being above the pre-war average, and interspersed with them, 19 months below it. In May and November, 1915, and May, 1916, the rates were exceptionally high. In the three years 1918-19-20, all but five of the 35 months are above the average, the highest rates being in May, 1919, and May, 1920, when the pre-war average was exceeded by 89 per cent. and 111 per cent. By December, 1920, the excess had diminished to 7 per cent.

Deaths.—Here we will only call attention to the Registrar-General's method of recording his facts. Three kinds of death rate are stated throughout the Report: (1) crude, (2) corrected, and (3) corrected and adjusted. The crude rate represents the number of deaths actually occurring in an area, the corrected rate is based on the deaths belonging to the area whether they occur within or beyond its bounds, and the adjusted rate compensates for differences between the age and sex distribution of the area compared with that of Scotland as a whole. From a table of the rates in the larger burghs two illustrations of the method may be given. In Clydebank the crude rate was 8.3, the corrected rate was 11.6, and the adjusted rate 13.4. Clydebank has very little institutional accommodation; its needs and when such deaths are

Then the age composition portion at healthy periods of life being high. When that is taken account of, and the standard applied is the age constitution of the whole of Scotland, the adjusted death rate emerges at 13.4. On the contrary the city of Perth receives into its institutions from the surrounding country many cases which die within its bounds but do not belong to it. When these are allocated to their own areas the crude death rate, which was 16.6, is reduced to a corrected rate of 14.4, whilst a further trifling reduction owing to age constitution gives an adjusted death rate of 14.1, or only 0.7 above Clydebank's, whereas its crude death rate of 16.6 was exactly the double of Clydebank's 8.3.

In concluding this notice we would only point out that the minimum death rates and infant mortality rates which Scotland has experienced in 1920 are still very definitely higher than those of England. What the causes are cannot be discussed here and now, but attention may be called to the facts as to housing stated in our notice of the Census of the Four Great Towns of Scotland in our issue of August 26th (p. 399).

EDINBURGH ROYAL MATERNITY HOSPITAL.

At the monthly meeting of directors of the Edinburgh Royal Maternity Hospital, held on September 19th, Dr. T. G. Nasmyth, chairman of the board, cordially welcomed Dr. B. P. Watson, the newly appointed professor of midwifery and gynaecology, who, under the arrangement between the university and the hospital, is *ex officio* a director of the latter. Professor Watson was further placed in charge of the hospital for the quarter beginning October 1st, with Dr. Oliphant Nicholson as assistant physician. Dr. J. W. A. Hunter was appointed senior house-surgeon and Dr. J. A. Douglas junior house-surgeon for the same period; the resident medical officers in the ante-natal department (under Dr. Ballantyne) were Dr. Rosemary O. Morris as senior and Dr. Ruth Ritchie as junior. The statistics of the hospital for the month of August were: Deliveries—intern, 168, extern, 80; at Leith branch, 31; total, 279. Attendances at ante-natal clinics—new cases, 115; revisits, 205. Attendances at venereal disease clinics—new cases, 15; revisits, 114.

Jamaica.

THE CENSUS OF 1921.

As it was not under a labour strike, Jamaica was able to have its 1921 census in April. Its population was found to be 858,118, an increase of 26,735 since 1911. But of the total increase no less than 22,201 was in the female population, and only 4,534 in the male. The males numbered 401,973, and

the females 456,145, or 113.4 per 100 males. The total inter-coastal increase was 3.2 per cent. As the rate of increase between 1911 and 1921 had been assumed to be a continuation of the rate which belonged to the period 1891-1911, when the growth had been much more rapid, the calculation for April, 1921, was 46,313 in excess of the census facts—as an example of the danger of that method of estimation. Evidently the excess of overseas departures above arrivals had been very incompletely reported to the authorities during the last decade. The population on shipboard at the census was 1,266, nearly half at Kingston. The British army population was 1,063 officers and men. The town of Kingston had 62,707 inhabitants, as against 57,379 in 1911. The next largest centre, Halfway Tree and vicinity, had a population of 25,337. The average number of persons per inhabited dwelling was 4.4. One-roomed houses increased to 80,654 from 75,670, but the criteria of housing are roofs—shingle, metal, concrete, or thatch—and the presence or absence of floors of concrete or wood. The best class has increased 20.5 per cent., the second class has decreased 1.8 per cent., and the lowest has decreased 22.3 per cent. Of the total population 17.2 per cent. consisted of married persons in 1921, as against 18.8 per cent. in 1911.

The population is divided into white, coloured, black, East Indian, and Chinese. There was a slight diminution in the number of the whites, from 15,605 to 14,476 in the ten years; their percentages to the total population were 1.88 and 1.69 respectively. Blacks, East Indian, and Chinese increased. A table of occupations shows that nearly one-half (48.3 per cent.) are classified as "indefinite and non-productive," but it is explained that these include children under 5, and many up to 14 years. Agriculture is the main occupation, and is followed by 33.3 per cent. of the population; the industrial class forms 8.6 per cent., domestic 6.1, commercial 2.4, and professional 1.3. Among the agriculturists bananas occupy the most workers; sugar comes next. Planters have increased from 112,542 to 129,312. Of persons from 5 years upwards 52.1 per cent. could read and write, 8.7 could read only, and 39.2 were unable to read. Of the total population 2,403 were born in the United Kingdom, and 2,264 were of British parentage.

The Registrar-General of Jamaica, Mr. David Balfour, is to be congratulated on having succeeded in obtaining so much interesting information for his census report.

Correspondence.

EXPERT WITNESSES: SURGICAL AND MEDICAL.

Sir,—May I be allowed to offer my support to Mr. C. H. Faggo's letter on Claydon v. Wood-Hill (September 16th, p. 531), bringing to the notice of your readers the vital importance to those who practise medicine of moving in the direction indicated in his "second point," where he speaks of "the hopelessness of the present method of employing medical experts on both sides of a case" and the disadvantage of calling medical evidence "for the plaintiff and for the defendant"? The defendant is usually the doctor who is the first to attend the plaintiff, and he has more intimate knowledge of all the circumstances and conditions of the patient than the medical experts who give their opinion for the plaintiff sometimes in support of an allegation of negligence in treatment. The plaintiff is entitled to be treated with due knowledge and, if there be negligence, he is likewise entitled to receive scientific and unprejudiced support from medical experts to establish his claim for damages. But the question that one so very frequently hears, and one that has for some time past aroused widespread feeling, is, Has not the time arrived when steps should be taken to put the trial of cases upon a more scientific basis than that existing at present time?

The British Medical Association, when it considered injustice had been done, has always supported members of the profession whether members of the Association or no has fought for the principle of equity. It is to be remembered that cases of alleged negligence are not confined to practice of surgery, and experts in the various branches of practice may be called upon to give evidence.

It may be of interest to those, like Mr. C. H. Faggo, who invited to give expert evidence in cases of alleged negligence to record my own experience when asked to give such evidence as a surgeon. For a time I flatly refused to see or have a

correspondence with a potential plaintiff, but on reconsideration I came to the conclusion for reasons I need not here state that it was not fair to a plaintiff who believed that I had special knowledge of the particular surgical conditions of the case. I therefore performed a *volte-face* and gave to the plaintiff the usual welcome I gave to ordinary patients; I took full notes of the case, and when my examination was finished I said: "I will send a copy of the notes I have taken to your doctor, and will ask him to come and discuss your case with me, so that I shall have full inside knowledge before deciding whether I can support your claim." I think I must have lost caste as a medical expert after adopting this plan, but I consider it to be the correct one, and believe that it might with advantage be imitated until the time arrives when Mr. C. H. Fagge's opinion shall fructify and it is generally recognized that "the present method of employing medical experts on both sides of a case . . . should be discontinued."

If the British Medical Association would take the initiative in organizing a committee, say, of its own body, with representatives from bodies granting qualifications to practise medicine, may I suggest that the body which appoints nautical assessors should be consulted with regard to the practice now existing in the Admiralty Court?

If the present persecution continues in respect to the results of the treatment of injuries to bones, the time will soon come when it will be wise for general practitioners to send all such cases to hospitals.—I am, etc.,

September 19th.

JOHN LYNN-THOMAS.

OPHTHALMIC EXAMINATIONS IN GENERAL MEDICINE.

SIR,—I will ask your permission to say a word in support of Dr. Tyson's commendation (p. 578) of the routine use, in clinical examinations, of the electric ophthalmoscope. To those to whom this form of ophthalmoscope has been of continuous service for a number of years it may at first sight seem superfluous at this time of day to speak of its values. Yet there is plain evidence of the existence of considerable areas of professional practice where these values are either unknown or ignored. One of the most impressive testimonies in this direction may be found in the recent issue of a volume on "ophthalmology," addressed to that much-exalted person the general practitioner. The author warns his readers that "all detailed ophthalmoscopic examination is practically impossible for the general practitioner," on account, *inter alia*, of hindrances to the inspection of the fundus "in the shape of various reflections from the mirrors, cornea, etc." But of the electric ophthalmoscope and of the ease and simplicity this instrument has lent to ophthalmoscopic examination our counsellor and guide has no information to offer. Against his counsel of despair I will select two relatively ancient quotations, the first from a review printed in your own columns:

"There is nothing inherently difficult in the use of the ophthalmoscope . . . and with a little practice any man of ordinary ability can acquire sufficient proficiency to diagnose gross changes in the fundus—such conditions, for example, as optic neuritis, optic atrophy, albuminuric retinitis, disseminated choroiditis, and massive haemorrhages."—BRITISH MEDICAL JOURNAL, July 4th, 1914.

And in relation to the electric ophthalmoscope:

"On a recent occasion when the All-India Sanitary Conference met in Madras a number of its members, who had not touched an ophthalmoscope for many years, were shown the fundus with an electric ophthalmoscope as simply and easily as they could have been shown a picture hanging on a wall through a hole in a partition. Not only so, but it is our practice to demonstrate the fundus with this instrument to lay visitors to the hospital."—Colonel R. H. Elliot, F.R.C.S., in *The Ophthalmoscope*, March, 1913.

This in 1913, and yet in 1922 one of our pastors and masters, ignoring the ophthalmoscope in its modern form, tells us from his pedestal that for the great majority of the profession ophthalmoscopic examination is "practically impossible." Evidently, therefore, Dr. Tyson's advocacy is by no means redundant or out of date. If I may add a personal word I would say, for numerous professional colleagues as well as for myself, that the "reflections from the mirrors and cornea" have not proved a hindrance to the easy and successful use of the electric ophthalmoscope, and even the "reflection" duo to "etc." has not asserted itself as an insuperable barrier.—I am, etc.,

London, W., Sept. 23rd.

C. O. HAWTHORNE.

STERILIZATION OF MENTAL DEFECTIVES.

The Medical Importance of Clearly Defined Biological Terms.

SIR,—I have read with much interest the correspondence on mental defect and sterilization, which began with Sir Archdall Reid's letter in the JOURNAL of August 26th. Some of the letters following his serve to illustrate the immense importance of Sir Archdall's clear, although condensed, exposition of his views concerning the great lack of precision in the terms used by nearly all writers on heredity.

The discussion concerning biological terminology, and on heredity in particular, which was published in *Nature* from time to time from November, 1920, to May, 1922, and is referred to by Sir Archdall in his letter to you, contains a full exposition of his contentions; and a study of it could not fail to be of high value to practitioners of medicine, most of whom have hitherto been mainly dependent on biological teaching for an understanding of the whole subject of heredity, with which they are necessarily and greatly concerned. In this discussion the importance of the distinction between "inheritance" and "reproduction" is brought out vividly, as well as the real meanings and applicability of the words "inherit," "innate," "acquire," "germinal," "somatic," and the like. All these are key-words. Without a clear understanding of their implications all controversy about heredity is futile. So also is all discussion of the question of sterilization of the feeble-minded.—I am, etc.,

London, W., Sept. 21st.

BRYAN DONKIN.

P.S.—This letter was written before seeing Sir Archdall Reid's letter in the JOURNAL of September 23rd.

EDINBURGH MILK SUPPLY.

SIR,—My attention has been directed to your issue of August 19th containing some extracts from the report of the Board of Health for Scotland during the year 1921.

The reference is chiefly to the quality of the milk in Scotland, and the figures given raise a presumption strongly adverse to the Edinburgh supply. Indeed, so large is the divergence as to lead me to suggest that the writer of the article referred to might have at once recognized that some fallacy underlay them, and have made such inquiry as was necessary to remove this before drawing the conclusions contained in the summary.

The actual fact is the figures cited are based on different sets of circumstances. Those applicable to Scottish cities generally represent adulterated samples in regard to which proceedings could be taken under the Food and Drugs Acts, while the higher figures applicable to Edinburgh represent the result of several analyses of each sample before any legal proceedings are instituted.

Thus each unit in the figure stated as being applicable to Edinburgh represents three and sometimes four samples of the same supply of milk purchased or procured at different places in order to ensure that the person guilty of the illegal act will be proceeded against and that the interests of the innocent vendor will be safeguarded. The writer of the article has been comparing things that differ, and thus forming entirely erroneous conclusions.—I am, etc.,

A. MAXWELL WILLIAMSON, M.D.,

Medical Officer of Health.

Public Health Department, Edinburgh, Sept. 19th.

** The matter is one between Dr. Maxwell Williamson and the Scottish Board of Health. We cannot agree that, having compared the text with the relevant table, it was our duty to make further investigation. The passage relating to milk samples in the official report, on which our own comments were based, is as follows:

"In the Burghs of Edinburgh, Dundee, Glasgow, and Aberdeen, the proportions of adulterated samples were 39.6, 8.8, 7.3, and 5.8 per cent. respectively. In the 12 other Burghs, with a population over 30,000, the proportion was 8.3 per cent., and in the remainder of the country 8.6 per cent."

From beginning to end of the report there is no hint of any "different sets of circumstances." We are pleased, however, to give Dr. Williamson the opportunity of making much-needed explanation.

PROMOTION IN THE R.A.M.C.

SIR,—A few weeks ago, having recently returned from abroad, I consulted the *Monthly Army List* for the whereabouts of some A.M.S. and R.A.M.C. friends, and what I noted led me first to study the *Quarterly List* and "Hart," and, secondly, to question certain men whose names I had not

found in the list. The net results of this study I venture to submit for your consideration. They are as follows:

1. Majors R.A.M.C. average greater length of service than majors in other corps of an allied kind, besides being older in years.
2. Some fourteen or fifteen A.M.S. colonels are being retained in the service beyond the time limit for this grade.
3. From the Medical Department list as a whole have disappeared the names of a considerable number of men, from among whom it seemed certain that several major-generals and probably a D.G. would sooner or later be chosen.

To put these facts in another way: (a) During the war a large number of senior officers were either brought back or retained beyond their time, and thus blocked promotion to substantive rank of the men below them. Now, four years later, and without any equivalent reason, a like condition still obtains. (b) This accounts for the exceptional oldness in the service of majors R.A.M.C., and explains the close approach to retirement age of sundry men above them. (c) Blockage of promotion means more than disappointment to individuals; it also spools possible grave loss to the service by some of those individuals (who may be officers of a specially desirable type) being led to resign. Some men of this order, including one or two whom I should class as brilliant, have in fact already left.

But this is not the only undesirable circumstance. Promotion above the rank of major and above the rank of lieutenant-colonel and colonel depends on "selection." Every officer can tell to a second the date on which his "batch" is due for promotion if there be no blockage and if no one is "passed over" or removed by death; but I have never yet known one who could predict how the selection factor would work out. In fact, no one in the service knows in what direction or directions he must shine if he hopes to obtain the votes of the selection board which will eventually decide his fate. The general impression seems to be that the essential thing is to have served under one or more members of the board and to have got on with them; in short, that promotion goes largely by favour. Without accepting this view I yet express a doubt as to whether even the board itself could state offhand to what touchstone or touchstones it applies the records of the officers concerned. Are they wide general experience? or success in administrative or executive positions in peace times, or the same on active service? or exceptional knowledge of some clinical, laboratory, or other special branch of work? or knowledge of languages? or a capacity for getting on with one's fellows?

It appears to me that in all public services in which promotion is by selection—and of these there are several—the points on which promotion depends ought to be thoroughly well known to every officer from the beginning of his career.

Finally, so far as the R.A.M.C. is concerned, I suggest that although it is a very popular service at the present time, and one of which most of us are proud, it will not so remain if the condition of matters herein described continues for any considerable further period. The existing blockage should be cleared away. The R.A.M.C. should set an example to all other services by making known what are the points on which selection is in question.—I am, etc.,

September 17th.

G. N. STEPHEN.

THE DETERMINATION OF SEX.

SIR,—Interest in the determining factor or factors in the production of sex naturally never wanes, and from time to time a new idea is mooted or an old one resuscitated. Some suggestions, such as that ova proceeding from a right ovary alone produce males, have been definitely disproved by observation, and others—for example, that the provision of an abundant supply of a particular form of nourishment to the mother will determine the sex of the embryo—are *prima facie* unlikely.

We may expect that in the production of sex it is inherently probable that the male will play as vitally important a part as the female, and both of the above suggestions are manifestly defective in allowing no part to the male.

Moreover, it is also to be anticipated that some natural law or laws will underlie the determination of sex, and further that such law or laws will not towards the equalization of the number of the two sexes.

For a long time past it has seemed to me that one simple suggestion, which I have not hitherto seen noted, fulfils the before-mentioned conditions, and it might be shortly stated as follows: That in the reproductive process each sex tends to

reproduce its opposite, the resultant of the strife between the two being the manifestation as to which had gained the upper hand. Thus if a male child results then the ovum has proved the stronger, and *vice versa*.

If my surmise is correct, and such a law does exist, then our interest would be more advantageously concentrated on finding out and investigating the factors which make for strength and for the gaining of the mastery. These factors are doubtless numerous, and possibly complicated, but my own observation leads me to believe that they will include not only such points as physical build and condition or acquired or inherited powers or weaknesses, but also such questions as relative age of the parents.—I am, etc.,

Manchester, Sept. 22nd.

R. W. MARSDEN, M.D.

ALOPECIA AREATA AND STRABISMUS.

SIR,—Dr. Goodwin Tomkinson has given us in your issue of September 16th, 1922, a most interesting family group of cases in which alopecia areata is linked with strabismus, the latter condition having been investigated by Dr. Hislop Manson.

To some of us who have followed Dr. Inman in his association of strabismus with a personal or family history of left-handedness or stammering, the record is of great importance. Dr. Inman has not selected at random certain eccentricities of childhood for special inquiry, but he has grouped a class of defects which he believes to be of psychological import.

It is clear from Dr. Tomkinson's cases that there were other psychical symptoms among them, the mother having suffered from "bilious" headaches, possibly migraine, as well as anaesthesia; five children also are stated to have been "nervous" and one a somnambulist. These indications are most suggestive. Obviously there is a line of research opening up which may yield valuable results if the various branches of the profession will contribute from various sources their experience as to analogous cases.

There is little doubt that if the cause is, as we suppose, psychological it should be dealt with by psychological methods; a great opportunity opens for practitioners who employ psychotherapy to find a solution of the problem.—I am, etc.,

London, E.C., Sept. 20th.

CHARLES F. HANFORD.

PSYCHO-ANALYSIS.

SIR,—The letter of Dr. Johnstone (p. 578) illustrates very well my point as to the necessity of educating the medical profession in the principles underlying modern psychotherapy.

Apparently he sees no difference between psychology as taught fifty years ago and the teachings of to-day, and it would take far more space than you could allow me to endeavour to bring his conceptions up to date. One cannot argue with a person who understands by the unconscious "the part of the brain for the moment inactive" as one would not be speaking the same language. The unconscious is dynamic, not static.

With regard to the possibility of the patient bringing hypothetical dreams to the analyst, this would not matter in least as the patient's inventions would be the outcome of mental processes exactly as are genuine dreams. As matter of fact we sometimes ask our patients to invent dreams when they can produce no other material. I think Dr. Johnstone will agree that the inventions of a poet or a novelist must bear a direct relation to the authentic psychological make-up, and the same is true of everyone. I am, etc.,

R. MACDONALD LABELL

Wyde Green, Birmingham, Sept. 23rd.

BACTERIAL FILTRATION.

SIR,—It has occurred to me that your readers might be interested to hear of a cheap and rapid method of filtering fluids containing bacteria in suspension.

Take an ordinary filter funnel, fold two thicknesses of stout good filter paper and almost fill up with clean sand (washed several times in a pan). Pour in water to make the sand settle down firmly and until the filtrate is colourless. (The colour is due to sand in suspension, fine enough to pass through the filter paper.) Scoop a cone in the firm sand, pour in the fluid cautiously so that

the fluid comes into contact only with sand and nowhere comes into first contact with the filter paper. Reject the first few filtrations.

Soluble protein should be tested for in urine one can read print through; but in bacilluria bacteria often remain in suspension even after centrifuging. The above method gets over this difficulty and does away with the necessity of candling.—I am, etc.,

TEMPLE GREY.

United University Club, Sept. 18th.

OPEN-AIR TREATMENT OF MEASLES: AN EXPERIMENT.

SIR,—Dr. Geo wrote in *Medical Lectures and Clinical Aphorisms*:

"Any mysterious change of type or epidemic constitution seems to be resolved so far as concerns measles into the condition of the air breathed by the patients."

During a recent epidemic of measles the cases that did worst were children shut off from light and air and heavily clothed.

The one case that did best was a delicate little girl that lay or sat up in bed lightly covered and under a big window, opened some eighteen inches from the top and with a badly fitting lower sash, so that light and air poured over her. One night when her fever and rash were at their height she kicked the bedclothes off and lay naked for some time till found so by her mother. There was no ill result. The rash did not go in. There were no pulmonary complications. Three days after the rash first appeared her tongue was clean, her appetite good, and she was playing with her toys. This quick return to health, as well as an easy time while rash and fever were on her, was in marked contrast to cases treated in what one would call a "well-ventilated" room; it was marvellous as compared with cases treated by warmth and stuffiness.

The above "experiment" was carried out by the mother. From what I read in my books, none of recent date, I would have hesitated to expose a case of measles so freely to currents of air and floods of daylight.

This case occurred at a time when the epidemic was at its height. In view of some articles recently in the *BRITISH MEDICAL JOURNAL* I should add the mother was giving cold water when I was called in.

The patient's younger sister took measles shortly after, and in a hot kitchen looked ill and coughed incessantly. At my suggestion she was given the same environment as the elder child had enjoyed, and with happy result. A cough mixture with paregoric, which was indicated, lay practically untouched, as the mother said the cough had almost ceased after the patient was transferred to the airy room.

—I am, etc.,

CHARLES J. HILL AITKEN, M.D.

Kilnhurst, nr. Rotherham, Aug. 31st.

SENIOR SURGEON COMMANDERS AND THE ADMIRALTY.

SIR,—The case of the senior surgeon commanders of the Naval Medical Service has been very ably represented by the British Medical Association, and your leading article of July 8th (p. 52) has placed all the salient points before members of the profession.

The Admiralty, by its curt refusal to remedy the grievances, and by its unjust treatment of those medical officers whose long and good service might, at any rate, have been thought worthy of some consideration, has shown that nothing less than pressure by the profession is necessary in order that these grievances may be removed and that regulations under which medical men elect to join the navy may not be treated as "scraps of paper." The only way in which pressure can be exercised is by medical men refusing to enter the service, and it will be the only way that will be understood by their lordships or the powers that be, whether bureaucrats, autocrats, or our own complacent people in their armchairs at the Admiralty, and until such pressure is exercised things will go on in exactly the same way.

But, surely, Sir, having placed the matter so ably before the profession, it is somewhat inconsistent for the *JOURNAL* to continue to insert Admiralty advertisements for medical officers for short service. If the conditions of the service were what they ought to be it would not be necessary to resort to this method of obtaining medical officers, and if the Admiralty can obtain men in this way it will not care about any warning from the British Medical Association.

I hope, therefore, that the *BRITISH MEDICAL JOURNAL* will not insert any further advertisements until the Admiralty has seen fit to mend its ways, to compensate those medical officers so unfairly retired before their time, and to give some guarantee that regulations shall not be treated as "scraps of paper."

The following is an extract from the Regulations for the entry of candidates for commissions in the Medical Department of the Royal Navy:

"Fleet Surgeon, Staff Surgeon, and Surgeon:
"Will be compulsorily retired as follows: At the age of 55, or any age, if he has not served for five years."

This is taken from the Regulations, dated June, 1890, and which those surgeon commanders who have been recently retired under the new order joined.—I am, etc.,

EXPERTO CREDE.

Obituary.

SIR JAMES AFFLECK, LL.D., M.D., F.R.C.P.,
F.R.C.S. EDIN.

Consulting Physician, Royal Infirmary, Edinburgh.

By the death of Sir James Ormiston Affleck, Edinburgh has lost one of her most skilled, highly honoured, and well beloved consulting physicians. For some months his friend had observed signs of failing health, but more recently Sir James was able to be about and was to have attended a consultation in the country on September 25th. His death in the end was sudden. He passed away in his sleep in the early hours of the morning of Sunday, September 24th. He exhibited in a high degree all the best features which were to construct the character of the physician of the late Victorian period—quiet dignity, courtly manners, knowledge founded upon close observation of clinical symptoms and upon a faculty of intuition, real sympathy, and unhurried advance to a treatment carefully thought out and all embracing in its scope. At the same time no one knew modern advances in medicine better than Sir James Affleck and no one could apply them more safely and satisfactorily and always with a touch of restraint, which was not without power. He could more than hold his own with the best of the Georgians, but his nature was not one in which "holding his own" had any personal significance, for no one was more unassuming and more ready to pay attention to every expression of opinion from another physician. He was essentially the physician's physician and the profession's favourite, and in his time he cheered countless sick beds amongst his brethren. When a well-known doctor in Edinburgh and neighbourhood was ill one had scarcely to ask whether Affleck had been to see him; it was taken for granted, so sought after and so helpful were his ministrations. In medical circles, in particular, his passing will be deeply felt.

James Ormiston Affleck was born in 1840 in the Stockbridge district of Edinburgh, not far from 38, Heriot Row, his home for many years and the place of his death. He studied at the university in his native city, and graduated there as M.B. and C.M. in 1867 and as M.D. two years later. In 1869, also he assisted Sir Douglas MacLagan, Professor of Medical Jurisprudence and Public Health, in his teaching. In the years following he began to lecture on the practice of medicine in Surgeons' Hall, and was elected assistant physician to the Royal Infirmary (in charge of the fever wards). He was elected a Fellow of the Royal College of Physicians in 1875, and at the time of his death his name was third in order of seniority on the Roll. He had already (in 1869) become a Fellow of the Royal College of Surgeons of Edinburgh.

In 1885 he became a full physician and a lecturer on clinical medicine in the Royal Infirmary, and during his term of office there he attracted many of the more thoughtful and earnest type of student to his wards and teaching; and so impressed were they with what he had to give them that they began after graduation to return more and more to him for advice. In this way he built up the large and important consulting practice which continued with him to the very end. He was also in touch with the University, acting from time to time as examiner in medicine and clinical medicine. On his retirement from the acting staff of the infirmary he was appointed one of the consulting physicians, and began to act for a time as physician to the City Hospital for Infectious Diseases. He was also physician to the Royal Edinburgh

hospital for incurables, and at the time of his death was the committee of management. Sir James Affleck was a member of the Medical Board for the Royal Edinburgh Asylum for the Insane, and for some years he acted as consulting physician to the Royal Maternity Hospital.

In all these public institutions he gave freely of his time, and energy. Thus, he had a great deal many years to do with the founding of the Longmore Hospital (for incurables); but he probably did most of all for the Royal Asylum, being on the board of management, playing a part as an unassuming one) in the various extensions and improvements, securing a bacteriological department, watching the welfare and housing of the nurses, and striving for efficiency and economy. His connexion with the Royal College of Physicians of Edinburgh was also long and helpful. For many years an examiner for the licence and the membership; and an active member of the Library Committee; he was for a long time on the Council of the College, and had been less retiring than he was he would almost invariably have occupied the presidential chair. His self-education, however, was not always such as to enable him to escape the recognition which was so ready to come to him. In 1908 the University of Edinburgh conferred upon him the honorary degree of LL.D., and three years later he received from His Majesty King George the honour of knighthood, to the great satisfaction of his many friends. He occupied the identical chair of the Edinburgh Medico-Chirurgical Society from 1905 to 1907. He was a member of the Edinburgh Branch of the British Medical Association, was president of the Section of Medicine at the Annual Meeting of the Association in 1896, when it met in Carlisle, was president of the Section of Pharmacology and Therapeutics in 1898, when the Association held its annual Meeting in Edinburgh. It was, again, perhaps his modesty which prevented him writing the textbook of practical medicine which he could so well have done, but he preferred to teach by word of mouth, and therein he excelled. At times, however, he took his pen in hand, as when he wrote many articles on medical subjects in the *Encyclopaedia Britannica* (ninth edition), when he gave contributions to the Medico-Chirurgical Society, and when he delivered his lecture address as president of that society. He had very something to say that was worth listening to on these occasions, and his address on "Nature's object-lessons in disease" was novel, brilliant, short, and thought-provoking. His paper on "Lobar pneumonia" read in 1907 was the work of a master hand, and was specially powerful in respect of diagnosis and treatment, as might indeed have been expected.

When one came into close contact with Sir James Affleck as a colleague, whether as student, as patient, as a tutor, or as a practitioner in search for further light upon a difficult illness, it was his sympathy, his unfailing and penetrating insight and understanding, and his resourcefulness which impressed one most, all of them combined with a shyness which was almost shrinking until the interest of the case or the strong feelings of the man brought his mind out into the open. He was not fond of what are called social occasions, but at home quietly no one could be more enterprising, for his mind was stocked with the best books and the best books, and from such stores he gave freely to them who showed an encouraging interest. His counsel on all matters, although he would not have admitted it, had an extraordinary weight; and over and over again one traced the same decisions back to Sir James as their source. What did "went." He was strongly although quietly religious, and could not be long in his company without discovering almost unconsciously.

He had a special interest in medical missionaries, and for many years acted as consultant physician in connexion with the Foreign Missions Committee of the United Free Church, and, again, few knew of this. He was likewise a great disposer with wonderful freedom not only money but time (often a more difficult gift) to almost everyone who asked. It has been said of him that he was almost an expert in putting lame dogs over stiles, but it remains to be pointed out that in so doing he seems to have cured also their lameness. No one who loved him could have wished for him a more peaceful ending than that which he had when he passed away in sleep at the ripe age of 82.

James Affleck was never married. Until her death many years ago his sister stayed with him. He is

survived by an elder brother, a retired minister of the United Free Church, formerly of Auchtermuchty. The funeral at the Dean Cemetery, Edinburgh, took place on Thursday, September 28th.

THE sudden death is reported of Dr. GEORGE HENRY SMITH of Knutsford on September 25th. He graduated M.B., C.M. Aberd. in 1875, and was medical officer of the Knutsford Workhouse and District of the Bucklow Union. He had a seizure while attending a patient. Dr. Smith, who was a member of the Mid-Cheshire Division of the British Medical Association, accompanied Sir H. M. Stanley's expedition to the interior of Africa in search of Livingstone.

THE death is announced of Professor J. J. MACKENZIE, head of the Department of Pathology in the University of Toronto, at the age of 57. Professor Mackenzie was educated at the University of Toronto and graduated B.A. in 1886 and M.B. in 1889. After taking post-graduate courses at Berlin and Leipzig he returned to Canada, and for some years was bacteriologist to the Ontario Department of Health. He was appointed professor of pathology and bacteriology in the University of Toronto in 1900. During the war he served with No. 4 General Hospital (University of Toronto), and while at work in Salonica the symptoms apparently began of the obscure illness which was to prove fatal. It is supposed that he suffered from streptococcal septicaemia, possibly due to pyorrhoecia. In the autumn of 1921 his condition became more serious and endocarditis developed. Professor Mackenzie was very popular with colleagues and students and was much beloved by those who knew him intimately.

THE death took place on September 2nd of Dr. ALEXANDER RITCHIE CRAIG, who had been secretary of the American Medical Association since 1911. Dr. Craig was born in 1868, and graduated B.A. in 1890 and M.A. in 1893 at Franklin and Marshall College, Pennsylvania, and M.D. at the University of Pennsylvania in 1895; in 1920 he received the honorary degree of D.Sc. from Franklin and Marshall College. Dr. Craig practised medicine in Philadelphia, and took a considerable part in the work of the American Medical Association, having been a member and chairman of many important committees. In 1911 he was elected secretary of the association, and from that time he devoted his life to its interests.

DR. ALAN KIDD, Superintendent of the Colombo General Hospital, died there on August 27th. He had recently been suffering from neurasthenia, and was on the point of going home on sick leave. He was educated at Queen's College, Belfast, where he held a medical scholarship, and graduated as M.B., B.Ch., and B.A.O. with honours in the Royal University of Ireland in 1909 and as M.D. of Belfast University in 1912. Entering the Colonial Medical Service, he was appointed to the island of St. Lucia in the West Indies, where he held the posts of resident surgeon of the Victoria Hospital, medical superintendent of the Lunatic Asylum, and bacteriologist, and after the war was appointed to Ceylon.

The Services.

DEATHS IN THE SERVICES.

Brigade Surgeon Lieut. Colonel William Price, Madras Medical Service (retired), died at Coonoor, in the Nilgiri hills, of heart failure, on August 25th, aged 76. He was born at Limerick on December 18th, 1845, and educated at Queen's College, Belfast, and at M.D. and C.M. in the Queen's University, Ireland. He was assistant surgeon on April 1st, 1870, and brigade surgeon lieutenant-colonel on April 7th, 1895. Before his retirement he held the post of Principal of the Madras Medical College, and Professor of Medicine therein.

Major William Joseph Tobin, R.A.M.C., was killed by a fall from his horse at Enniskillen on September 20th, aged 41. He was born on November 23rd, 1880, and, after taking the L.R.C.P.I. and L.R.C.S.I. in 1905, entered the R.A.M.C. as lieutenant on February 4th, 1908, attaining the rank of major after twelve years' service. He served in the war of 1914-18, was mentioned in dispatches in the *London Gazette* of August 15th, 1917, and held the acting rank of lieutenant-colonel for two years—from November, 1916, to December, 1918.

Medical News.

DR. B. H. SPILSBURY, whose lectureship in morbid anatomy and histology at St. Bartholomew's Hospital has recently been altered to a full-time appointment, and who in consequence is relinquishing the pathological work done by him on behalf of London coroners, has been appointed Honorary Pathologist to the Home Office in order that his services may still be available for criminal cases of special difficulty.

THE first of the new series of post-graduate lectures for the autumn session will be given in the West Lecture Hall, Royal Society of Medicine, 1, Wimpole Street, W.1, on Wednesday, October 11th, at 5 o'clock, by Sir James Galloway, on "The symptoms and treatment of certain unexplained granulomatous diseases." Further lectures have been arranged as follows: Dr. Eric Pritchard, "The feeding of infants from birth to the end of the second year"; Dr. Lakin, "Indigestion"; Mr. Zachary Cope, "Some important but ignored symptoms in acute abdominal disease"; Dr. S. A. Kinnier Wilson, "The old motor system and the new"; Mr. J. D. Mortimer, "The medico-legal position of the anaesthetist." Copies of the detailed programme can be obtained from the Secretary to the Fellowship at the above address.

It is announced that the opening of the new biological department of McGill University, Montreal, next month will be attended by Sir Charles Sherrington, G.B.E., M.D., President of the Royal Society.

THE programme of lectures and discussions arranged by the Child-Study Society, London, has been issued. The meetings are held on Thursdays at 6 p.m., at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1. The session begins on October 5th with a lecture by Dr. C. W. Kimmins on "Visual humour." The three following meetings—October 19th and 26th and November 16th—will be devoted to the discussion of mental tests and the measurement of intelligence in children. On November 30th Dr. A. F. Tredgold will lecture on "Some problems relating to mental deficiency."

THE Scottish Board of Health has issued a report on the administration of the Sale of Food and Drugs Acts for the year 1922. This contains an abstract of the reports of public analysts for the previous year, and it is intended that a separate document of this kind should be published each year. The price of the report is 3s., and it is stated that unless there is a sufficient sale the publication in future years will not be permitted owing to the need for economy.

THE post-graduate lectures which have been given at the Manchester Royal Infirmary during the past few years will be continued this year, commencing on October 3rd. Besides the weekly lectures on general subjects given by the members of the honorary staff, a special course of six lectures on nervous disease will be given by Dr. Reynolds. This course will take place on Fridays, beginning October 6th.

As already announced, a national conference on the milk supply will be held in the Council Chamber of the Guildhall on Monday, Tuesday, and Wednesday, October 16th, 17th, and 18th. All who are interested in the milk question and who desire to attend this conference should write for the necessary application form to Miss H. M. Willans, Honorary Secretary, 3, Bedford Square, London, W.C.1, as admission is only by ticket obtainable on or before Thursday, October 12th; no tickets will be issued during the conference itself either at the Guildhall or at 3, Bedford Square. Accommodation is limited and early application is desirable; this applies both to members of the conference and non-members, to whom tickets will be issued in order of application, though members' tickets will be given out first.

THE next meeting of the Society for the Study of Inebriety will be held in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Tuesday, October 10th, 1922, at 4 p.m., when Colonel L. W. Harrison, D.S.O., M.B., will open a discussion on "The relation of alcoholism to venereal disease." Each member and associate is at liberty to introduce visitors.

THE annual conference of the Guild of Health opens to-day (September 30th) at Girton College, Cambridge. The papers set down for discussion include one on "Auto-suggestion—its benefits and dangers," by Dr. William Brown, Wilde Reader in Mental Philosophy in the University of Oxford.

A FIFTH course of lectures for the diploma of Psychological Medicine will be held at the Maudsley Hospital, Denmark Hill, S.E.5. Part I of the course will commence on Tuesday, October 10th, at 2.30 p.m., when Sir Frederick Mott, K.B.E., F.R.S., will give the first of eight lectures on the anatomy of the nervous system; the other seven lectures will be delivered on succeeding Tuesdays at the same hour. Dr. F. Golla will deliver eight lectures on the physiology of the nervous system

on Fridays at 2.30 p.m., commencing on October 13th. Eight lectures on psychology will be delivered by Dr. Henry Devlin on Thursdays at 2.30 p.m., commencing on October 12th. Practical instruction and demonstrations will be given at each lecture. Part II of the course will follow in January 1923.

DR. H. CRICHTON MILLER will give a course of ten lectures on elementary psychotherapy at the Tavistock Clinic for Functional Nervous Cases, 51, Tavistock Square, W.C.1, on Mondays, at 5.15 p.m., beginning on October 16th. Dr. J. A. M. Alcock will also give a course of six lectures on symbolism on Wednesdays, at 5.30 p.m., commencing on October 18th. The fee for the former course is £2 2s. for medical practitioners and £1 1s. for medical students, and for the latter course £1 1s. Tickets can be obtained in advance from the Honorary Secretary at the clinic.

THE annual service in connexion with the Guild of St. Luke will take place at St. Paul's Cathedral on Wednesday, October 18th, at 7 p.m., when the Rev. Lord Victor Seymour will preach. The offerings, after defraying the cost of the service, will be devoted to the Cathedral Repair Fund. Tickets may be obtained from the Guild Secretary, the Rev. H. Kirkland Whittaker, M.D., Chaplain's House, Banstead Downs, Sutton, on sending stamped addressed square envelope.

THE Minister of Health has issued an Order (No. 1026 of 1922) rescinding the Health Visitors (London) Order, 1909, under which the Local Government Board made regulations for the qualification, appointment, duties, salary, and tenure of office of health visitors in London.

At the Congress of Nursing and Social Medicine held at Bruges on August 7th an International Midwives Association was formed with the following members of council: Professor Frans Daels of Ghent, Dr. Panto of The Hague, Miss Emily Ford of London, and Mrs. van der Elze of Haarlem.

At a meeting of medical women held recently in Toronto preliminary steps were taken to form a Canadian Medical Women's Association. Dr. Sproule-Mason was appointed acting president and Dr. Isabel Ayre of Toronto was appointed acting secretary. Dr. Jennie Smilie attended the recent International Conference of Medical Women at Geneva (reported in the SUPPLEMENT of September 16th, p. 111) as a delegate from this Canadian association.

THE Medical Golf Cup Tournament at Llandrindod Wells was brought to a successful conclusion on Thursday, September 21st. The weather was delightful throughout the competition. Dr. Hugot (Pennard) and Dr. Baird (St. Leonards) were the finalists, the former winning on the last green. The cup (value 50 guineas) was presented by Lieut.-General Sir Herbert Watts, K.C.B., K.C.M.G. The competitors were entertained to dinner at the Hotel Metropole by the local committee on Thursday evening.

THE annual conference of the Chartered Society of Massage and Medical Gymnastics will be held in London on October 5th, 6th, and 7th. Lectures will be given at the Steinway Hall, Lower Seymour Street, Portman Square, by Sir W. Arbuthnot Lane, Mr. R. C. Emslie, Sir Maurice Craig, and others. A demonstration will be given in the physiotherapeutic department of St. Thomas's Hospital, and a demonstration of gymnastic class work for curative purposes at the Chelsea College of Physical Education. The secretary of the society is Miss E. M. Templeton, 157, Great Portland Street, London, W.1.

THE inaugural meeting of the Guy's Hospital Pupils' Physical Society will be held on October 12th at 5 p.m., when Sir Charters Symonds will give an address on "Some Guy's surgeons and their writings," with portraits and other illustrations. Sir William Hale-White will be in the chair. We note with interest that a joint clinical and pathological meeting with the Physical Society of St. Thomas's Hospital is to be held on November 30th.

DURING 1921 596 cases of small-pox occurred in Switzerland, with 8 deaths. Of the patients 23 were vaccinated, 16 had been revaccinated, 359 were unvaccinated, and in 198 no information could be obtained. Of the 8 fatal cases 7 were unvaccinated and 1 revaccinated.

THE St. Louis Emergency Relief Committee for German and Austrian universities has made a donation of 30,000 marks to the University of Halle.

THE will of the late Sir Edward Malins, M.D., Emeritus Professor of Midwifery in the University of Birmingham, who died in July last, has been proved; he left net personalty of £20,458.

THE annual dinner for past students of the London Hospital will be held on Thursday, October 12th, at 7.30 p.m., at the Trocadero Restaurant, with Sir Arthur Keith, M.D., F.R.S., in the chair. The honorary secretaries for the dinner are Messrs. H. S. Souttar and E. C. Lindsay, from whom tickets can be obtained.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

Correspondents who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

Persons desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

the postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, Attilioley, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, Medisecra, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 36, South Frederick Street, Dublin (telegrams: *Medisecra, Dublin*); telephone, 4737, Dublin, and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*); telephone, 4261, Central.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

QUERIES AND ANSWERS.

ASTHMA.

IN JAMES DUNDAS GRANT, replying to an inquiry regarding the development of asthma after the removal of nasal polypi (JOURNAL, September 23rd, 1922, p. 532), refers to a paper on nasal diseases in relation to asthma which he published in the *Practitioner* of June, 1913. He stated there that the incomplete removal of polypi had been known to wake up a quiescent asthma, and, indeed, that asthma was found sometimes to be relieved by removal of a small polypus, and quite unaffected by the clearance of large ones. The explanation was probably that a small polypus might, by intermittent contact, "tickle" the sensitive areas of the mucous membrane in the way that a large polypus in continuous and equal contact might fail to do. A small remnant of polypus might, therefore, act in the former way until it was completely removed.

INCOME TAX.

"X. G. S." writes: The assessor has added the rental value of my sanatorium to the amount assessed by him under Schedule D, although it is assessed under Schedule A; is this correct?

"X. G. S." does not say for what purpose the addition is made; presumably, in calculating the amount of profits to be assessed under Schedule D, the amount of the Schedule A assessment was deducted as the rent equivalent, and, consequently, if the total profits have to be ascertained, the two assessments must for that purpose be added together.

"P. and Q." were in partnership on the basis of equal shares, though "Q." accounted for two-thirds of the receipts; "Q.'s" share has been sold, and "P." is now separately assessed on the basis of half the profits of the former combined practice.

"P." is undoubtedly liable in respect of the past profits of the practice as now constituted, and he has a right of appeal to the Local—or, if preferred, to the Special—Commissioners, who would no doubt hear an accountant on his behalf if he wished. If the professional expenses borne by "P. and Q." were in the same ratio as their cash receipts then it is clear that "P.'s" practice is only one-half as profitable as that formerly carried on by "Q." On any other hypothesis the facts must be gone into in detail somewhat as follows: If "P.'s" gross earnings were £1,000 and his expenses £x, and "Q.'s" expenses were £y, then "P.'s" assessment should bear the same ratio to "R.'s" assessment as £1,000 - £x bears to £2,000 - £y. At the same time "P." will, of course, understand that he can appeal only in respect of his own assessment, and that he may have to confine himself to showing what is the average profit of the "P." practice, without direct reference to "R.'s" assessment, which, strictly, is not in issue. This he can do by taking the average profit as measured by the excess of the fees paid on account of his practice over his expenses.

THE PORTUGUESE RIVIERA.

Dr. ST. GEORGE B. DELISLE GRAY, M.O. in charge of British Hospital, Opôrto, writes: In answer to "M.D.'s" question (August 19th, p. 332) about the Portuguese Riviera for bronchitics, I think his patient would find it most suitable. Mont Estoril has quite a delightful climate and is a winter resort. Cintra has quite a delightful climate and is a winter resort. The cost should be avoided on account of its liability to mists. The cost

absurdly cheap; but no doubt English visitors would cause prices to rise if they came out in any numbers. The Portuguese are great bargain-hunters, and always ask much more than they are prepared to accept. Hotels vary very much in accommodation, cleanliness, and culinary arrangements. At Mont Estoril they are supposed to be quite good. English visitors will have to shut their eyes to much, especially in the more rural parts of the country. Sanitation frequently leaves much to be desired. I believe a good many English visitors go to Mont Estoril during the winter, so that his patient need not feel isolated. In addition, it is within easy reach of Lisbon, which is a fine modern city. Last month my wife and I put up at a first-class hotel in Lisbon for the inclusive charge of 10s. per day each; this I remark just to give some idea of prices.

Portugal is a very beautiful country with many historic associations, especially for the British. The Portuguese are an extremely courteous race and expect to be treated with politeness, especially in their own country. They are most considerate to strangers, but resent being looked upon as foreigners by British and other visitors to Portugal, as is too often the case. My relations with them have always been the pleasantest, and I have received nothing but courtesy and kindness from them in all my dealings. Many speak English, more speak French. For further details I would refer to the following works by Delgado: *The Climate of Portugal*, Lisbon, 1914; *The Climate of Lisbon*, Mont Estoril, and Cintra, London, 1934; *Notes on the Climate of Mont Estoril and the Riviera of Portugal*, Lisbon, 1908. They will probably be in several public libraries, and almost certainly in the library of the British Museum. I shall be very glad to give any further information.

LETTERS, NOTES, ETC.

HERPES WITH FACIAL PARALYSIS.

DR. J. OWEN WILLIAMS (Glanrhyf, Cardiganshire) writes: As bearing upon what Dr. J. F. Gordon writes (September 16th, p. 538), I may say I have during this last month had two cases of herpes in youths over the regions which he names (but perhaps not so extensive locally), and each has completely recovered. They were both on the left side. It is possible that the age of his patient—72 years—may have made him more liable to the facial paralysis.

A VACUUM FLASK FOR WARMING GAS IN PERITONEAL INFLAMMATION.

DR. F. HERNIMAN-JOHNSON (London, W.) writes: I regret that in describing a method of warming gas in peritoneum (footnote to report of JOURNAL, September 16th) I got the idea of the thermos flask from a use one in his anaesthetic work.

URINE TESTS.

DR. G. WASHINGTON ISAAC (London, W.C.) writes: Some inconvenience arises when using Fehling's solution (two bottles) owing to the fact that the stoppers of the bottles become fixed by the crystals that form around them; these crystals, by hygroscopic or capillary action, draw the fluid up and it runs down the outside of the bottle and makes a mess. The application of soft or hard paraffin to the washed and dried stoppers prevents them for a time from becoming fixed, but interferes with a smooth flow of the fluid over the edge of the lip, so that it is impossible to measure a small quantity accurately. For albumin I chiefly use acetic acid, brine, and heat, and here again I am troubled by use acetate of sodium chloride which form all around the crystals of the drop bottle and interfere with the free passage of stopper of the drop bottle and interfere with the free passage of the solution, and if one presumes the stopper the solution will not drop. Perhaps a chemist will be good enough to say whether these inconveniences could be removed by the addition of glycerin without upsetting the accuracy of the tests.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 30, 31, 34, and 35 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 32 and 33. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 129.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be paid for by the Post Office to receive posts is or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

224. Cases of Varicella following Herpes Zoster.

ARNOLD NETTER (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, July 6th, 1922, p. 1004) refers to 2 patients brought before the society by J. Pignot and H. Durand (p. 1002), and to his previous communication to the Academy of Medicine (June 29th, 1920, and May 16th, 1922) on the relations of varicella and zona. Netter now gives particulars of 9 hitherto unpublished cases, which, added to those already reported, makes a total of 26 French cases. In support of his argument he states that for the first time he has seen generalized varicella appearing on the fourth day in a case of herpes occipito-cervicalis. The details of his second case are remarkable. A Paris physician who does not practise general medicine and is not likely to be exposed to infection, in December, 1921, had an attack of herpes cervicalis which prevented him from carrying on his hospital or private practice for fifteen days; he went out for the first time on December 20th. On December 22nd or 23rd his daughter, aged 3, developed varicella, and on December 24th his son, aged 1 year, developed the same disease. Under these circumstances Netter concludes that it is very difficult to imagine any other origin for the children's illness than that they were infected by their father. After giving details of the other cases, which resemble those already reported by numerous observers, Netter concludes by quoting Elliott's paper (*Glasgow Med. Journ.*, May, 1922) on five outbreaks of chicken-pox in a fever hospital in the period 1914-21 following admissions of cases of herpes. Netter regrets that he has been unable to compile similar statistics from his own hospital registers, but in 1919, 1920, and 1922 he saw chicken-pox follow herpes in three cases. "We have not only proved that cases of varicella may appear among the 'contacts' of patients suffering from herpes. We have shown that the sequence is frequent, provided that among the 'contacts' there are persons susceptible to varicella—that is, who have not been immunized by that disease." Netter's case of concurrent herpes and varicella is as follows: "A concierge, aged 60, had violent pain on the left side of his head and ear for forty-eight hours; he then developed two red patches, as large as almonds, on the same side of the scalp near the middle line; on these a few small vesicles formed, followed by typical vesicles in the external meatus and behind the ear. The doctor who saw him next day diagnosed herpes, but four days later found a generalized vesicular eruption, so severe that the case was notified as one of small-pox. The absence of lumbar pain and vomiting and the mildness of the constitutional disturbance, together with the remains of the herpetic eruption, caused Netter, who saw him in consultation a week after the generalized eruption appeared, to change the diagnosis to varicella. At the meeting of the society at which Pignot and Durand presented their cases Comby protested strongly against the astonishing theory 'that the association of herpes and varicella was other than fortuitous.' In forty years I have seen thousands of cases of varicella and scores of cases of herpes, but I have never seen the coincidence of these two affections."

225. Acute Leukaemia.

W. BERBLINGER (*Klinische Wochenschrift*, July 15th, 1922, p. 1449) points out that, though cases of leukaemia may be divided by their clinical course into acute and chronic forms, histologically they do not greatly differ. Both the acute leukaemic myelosis (acute myeloid leukaemia) and the acute leukaemic lymphadenosis (acute lymphatic leukaemia) are characterized by the abrupt onset of severe general symptoms, with fever and haemorrhages in the skin and from the mucous membranes. In the acute forms the number of white corpuscles is less than in the chronic forms. In the acute myeloid leukaemia the white cells are chiefly myeloblasts, with many transitional forms between these and myelocytes. STERNBERG considers that acute myeloid leukaemia is not a definite disease. He thinks the symptoms are due to septic infection, especially by streptococci, and that the symptoms of acute lymphatic leukaemia are due to a general infection. Berblinger records six cases, four of which by their course and the blood conditions can be regarded as acute myeloid leukaemia. In the sixth case the blood was found normal just before the onset of the symptoms of the disease, and the duration up to the fatal termination was only about eight weeks; accumulations of cells, myeloblasts; and myelocytes

were found between the muscular fibres of the diaphragm. No bacteria were found in the blood or in sections of the organs in any of the cases. Also the post-mortem changes did not correspond to those of sepsis in any of the cases. From his observations the author concludes that we must admit the occurrence of acute myeloblastic leukaemia on the grounds of the clinical course, the blood examination, and the histologic changes.

226. Neuro-syphilis in Ex-Service Men.

R. H. PRICE (*Journ. Nervous and Mental Dis.*, June, 1922, p. 485) summarizes the experience gained in the treatment of over 80 cases, incident to military service, at the United States Public Health Service Hospital No. 49, Philadelphia. Following upon a six weeks' course of neo-salvarsa intravenously, with mercurial inunctions and potassium iodide, spinal drainage was instituted, while each case, rather than the disease, was treated by regulating the diet, exercise, etc., and improving the physical tone with hydro and electro-therapy. Two years' treatment is necessary before any positive conclusion can be arrived at as to the prognosis or value of specific therapy. Of 12 cases treated regularly for one year 4 showed no improvement, while of the remainder none actually recovered, though they showed varying degrees of change for the better either mentally, physically, or both. The blood Wassermann became negative in 3 and the spinal fluid Wassermann negative in 2. Of the 12 patients treated regularly for a year or more by spinal drainage only 2 showed no reduction in the gold curve on blood count, the latter being reduced much sooner than the former, it taking three months to produce any reduction in the gold reaction, so that it is only by lengthy trials that the value of various forms of therapy can be determined. Definite results as to treatment cannot as yet be stated in respect of the rest of the 80 cases, since the time is too short to draw any conclusion as to prognosis. In less than a year 1,575 Wassermann reactions, 868 spinal punctures, and 1,355 intravenous injections were conducted. Opinion of authorities divided as to the value of intraspinal therapy, Dercum and Gilpin considering that repeated spinal drainages, combined with medication other than intraspinal, are of benefit, while Lowrey holds that intensive intravenous therapy gives the best results, intraspinal therapy being chiefly of value in early painful cases, spinal drainage being useful in cases which would react well to any form of intensive treatment but of no value in others.

227. The Tuberculin Reaction.

J. A. KOLMER (*Therapeutic Gazette*, June 15th, 1922, p. 381) in discussing the nature of the tuberculin reaction and its use in diagnosis and treatment of tuberculosis, remarks that the local and focal reaction to tuberculin is allergic shock which by its effect upon the vasomotor system causes hypæmia around the foci of the disease, the constitutional reaction being the result of increased absorption of poison from these foci. These reactions are highly diagnostic and specific, since they occur only in tuberculosis, with less than 3 per cent. of error, which is due to the fact that allergic sensitization may be set up by undetectable, possibly microscopic lesions. While the focal reaction is useful in the clinical diagnosis of lesions, positive local skin and mucous membrane reactions show the presence of tuberculosis without indicating the locality of the lesions. Specially useful in diagnosis in children, the value of these reactions decreases as age advances. In advanced and acute tuberculosis the reaction may be negative owing to desensitization by absorption from the foci, and reactions may become negative during immunization, or from the production of sufficient fibrous tissue around the foci to prevent absorption. While a slight degree of immunity to later infection may be engendered by the insoluble tuberculins in which the dead bacilli exist in suspension, there is no proof that Koch's old tuberculin confers any immunity against virulent bacilli. Anything which favours the production of hyperæmia and serous and cellular exudation around the foci of disease is of therapeutic value, and tuberculin is especially useful in the treatment of chronic or localized cases, but it is important that the doses should be so small and so spaced as to produce only a mild, but more or less continuous, focal reaction and slight constitutional effects. It is in such mild allergic tuberculin shocks, which favour the production of fibrous tissue, that the value of tuberculin in suitable cases lies.

the kidneys. From such embolic foci the disease spreads to other parts. The success following nephrectomy points to the correctness of this view, for were the disease contracted in the process of eliminating a chronic blood infection with tubercle bacilli nephrectomy would surely be of little avail.

235. Diverticulitis of the Colon.

R. NEIRYNCK (*Journ. de radiol. et d'électr. méd.*, June, 1922, p. 293) states that Carman and Case in 1914 were the first to describe the radiological appearances of this rare affection, which it is impossible to detect by ordinary clinical examination. The diverticula, which are almost always multiple, may be found on any of the segments of the colon, but are most frequent on the descending colon or sigmoid. They are usually associated with more or less secondary inflammation. Their presence is revealed by the usual method of examination—namely, administration of barium by mouth or rectum. Pictures taken from fifteen to thirty-nine hours after the meal show a narrowing of the lumen (due to secondary colitis), external to which are to be seen small projections, which are round or oval, sessile or pedunculated. Their persistence several hours after evacuation of the colon is characteristic of diverticulitis.

236. Steinach's Epididymectomy for Senile Decay.

SAND (*Ugeskrift for Læger*, June 1st and 8th, 1922) has performed Steinach's operation on fifteen cases since September, 1920. Ten patients were suffering from ordinary or premature senile changes, and five from such conditions as impotence, depression, failing memory, and the like. Realizing that vasectomy at any level might merely lead to the formation of cysts without inducing the desired changes, the author resected the vas as near the testicle as possible, dissecting out the epididymis and carefully avoiding injuries to the vessels and nerves before the vas was divided and the ends were cauterized. The operation was performed under local anaesthesia and both sides were operated on only in some cases. No ill effects were observed apart from a slight feeling of tension in the parts concerned for a short time after the operation. The patients being a motley group, and exhibiting a great variety of morbid changes other than those for which they were operated on, and the actual indications for operation also varying considerably, it was very difficult to form a correct opinion of the results achieved. In some cases they were quite negative. In others they were strikingly beneficial, depression and inability to concentrate vanishing, and potentia coeundi returning or becoming more lively than before. One patient married again on the strength of these changes.

OBSTETRICS AND GYNAECOLOGY.

237. Endometrial Haematoma of the Ovary.

J. V. MEIGS (*Boston Med. and Surg. Journ.*, July 6th, 1922, p. 1), from a study of 16 specimens removed at operation, is able to confirm Sampson's views that perforating haemorrhagic (chocolate) cysts of the ovary are in many instances due to the presence in this organ of menstruating endometrial-like tissue. In Meigs's cases, as in Sampson's, the majority of patients were aged over 30, and sterility was relatively common; two only had reached the menopause. Six patients complained of dysmenorrhoea, 4 of menorrhagia of recent origin, and 6 of abdominal pain; in one only did the endometrial haematoma form a clinically palpable tumour. Uterine retroposition was demonstrable in 9 cases. If antecedent gonorrhoea can first be ruled out, endometrial haematoma of the ovary, it is said, should be susceptible of diagnosis in 50 per cent. of cases from the history and physical findings. The cysts measure from 1 to 12 cm. in diameter, but are not usually larger than 4 cm.; they are nearly always situated on the lateral surface or free border of the ovary. Periovarian adhesions are always found, and nearly always the cyst has perforated; the contents are typical—dark, chocolate-coloured, or tarry fluid. Microscopically, the endometrial tissue which can be recognized in the ovary shows a layer of cuboidal, columnar, or cylindrical epithelium resting on a tissue composed of blood vessels and loose connective substance, with abundant old and recent extravasations of blood. Sampson finds that these cysts are capable of implanting early adenomata of endometrial type on the peritoneum at the site of adhesions about the perforation, and he has found at distant portions of the pelvic peritoneum small blood cysts histologically identical with those in an adenocarcinoma of the Fallopian tube, the surface of the mesosalpinx, and the sigmoid or other portions of the bowel are in some instances the result of invasions by these implanted cysts. In 4 cases of Meigs's series adeno-

leiomyoma was present in one of the above-named situations and in 1 case the peritoneal implantation was verified microscopically. Probably the endometrium of the cysts is governed by ovarian secretion; it shows phasic menstrual variations, and Meigs reports that in one case implanted nodules in the rectum disappeared after castration.

238. Cysts of the Corpus Luteum.

R. KELLER (*Gynecol. et Obstét.*, 1922, v, 6, p. 458), from a microscopical study of 27 corpus luteum cysts of the ovary, concludes that the different types of these cysts described by Schill and by Fraenkel are explained by the varying histological characters shown at different stages of development of a structure which is typically uniform. The external layer of the cyst wall is composed of vascular connective tissue which may contain recognizable cellular remnants of the theca externalis. Internal to this is the layer of luteum cells, which in older cysts acquire a characteristic arrangement, due to penetration of vascular ingrowths of connective tissue from the external layer. Still nearer the interior an investment of connective tissue of embryonic character may or may not be present. This layer has erroneously given rise to the description of an innermost endothelial or epithelium lining, which, according to Keller, does not in fact occur. A causal connexion has been suggested between corpus luteum cysts and pathological nidation of the ovum, giving rise to ectopic pregnancy; Keller, however, in large series of cases, found the occurrence of the cysts to be equally as common in ovaries removed for adnexal inflammatory conditions as for extrauterine gestation, and in 13 cases only of 150 ectopic pregnancies was a lutein cyst present. The formation of the cysts is explained by the writer as being due to defective development of lymph spaces in connexion with the outer layers of the wall; absorption of the fluid contents is thereby impeded. Lutein cysts are commonly present in cases of hydatidiform mole and chorion-epithelioma; they take up the major part of the ovary and have a scanty lutein-cell layer. The formation of the mole precedes that of the cyst, which is probably to be ascribed to follicular degeneration.

239. Cullen's Sign of Ruptured Extrauterine Pregnancy.

J. P. ZUM BUSCH (*Deut. med. Woch.*, July 14th, 1922, p. 941) discusses the sign first described by Cullen of Baltimore in 1919. It consists of discoloration of the skin about the umbilicus. Being found associated with free blood in the peritoneal cavity following rupture of an extrauterine pregnancy, it has been regarded as suggestive of such a rupture, and pathognomonic of an effusion of blood into the peritoneal cavity. The author records a case to show that this view is incorrect. His patient was a woman, aged 60, who showed signs of the acute abdomen. In addition to violent pain and retention of flatus and faeces, there was a bluish-green discoloration, with a yellow tint, about the umbilicus. Laparotomy revealed a large ovarian cyst which had become twisted on its pedicle. The cyst, which contained almost black haemorrhagic fluid, was slightly adherent over an extensive area to the anterior and lateral abdominal walls. There was no free blood in the peritoneal cavity. Thus the discoloration of the umbilicus due to absorption of effused blood cannot be traced to invasion of the peritoneal cavity with blood.

240. Pregnancy and Addison's Disease.

G. FITZ-PATRICK (*Surg., Gynecol., and Obstet.*, July, 1922, p. 72) summarizes the eleven cases which have been recorded in the literature of Addison's disease complicating pregnancy or the puerperium, and records a personal case. A primipara, aged 28, began twenty hours after labour to manifest irregular pyrexia first ascribed to septic endometritis. Eight days later deep cutaneous pigmentation, mental lethargy, asthenia, and diminished blood pressure were all well marked. The influence of pregnancy and labour on Addison's disease is frankly bad, if one judges by the recorded cases, in five out of eleven of which the mothers died before they had reached term or within a few days after labour. It is probable that pregnancy may act as a stimulus rendering a latent Addison's disease manifest in a patient whose suprarenals are already faulty; cases in which the disease has been recognized before pregnancy appear to undergo an intensification of the signs and symptoms during the gravid condition. Foetal prognosis is bad because of the frequent occurrence of abortion. In none of the cases was there uterine atony or insufficiency at or after labour, so that if adrenaline plays any part in the mechanism of labour the conclusion must be drawn that the loss of adrenaline of suprarenal origin must have been compensated for in some unknown manner. The writer's patient showed considerable improvement after exhibition of suprarenal and thyroid extracts.

R. M. STEWART (*Journ. of Neur. and Psychopath.*, August, 1922, p. 144) reviews the present state of knowledge of this subject, observing that greater advances have been made in its pathology than in its physiology. In the course of an exhaustive review (to which is appended a very complete bibliography) Stewart arrives at the following conclusions: (1) On the whole there is almost complete unanimity of opinion that the choroid plexuses are the chief source of the cerebro-spinal fluid. This conception rests not on any single conclusive piece of evidence, but on well-established data derived from histological, pharmacological, and pathological observation. (2) The question whether the cerebro-spinal fluid is a true secretion or a dialysate cannot as yet be fully answered. (3) The possibility of subsidiary sources of supply, either by drainage from the perivascular spaces or from the membranous surfaces of the brain, must be considered. (4) Conclusive proof that the cerebro-spinal fluid functions as the lymph of the brain is at present lacking. (5) Thus far the methods devised for computing the rates of formation and absorption are unreliable. (6) Absorption of cerebro-spinal fluid takes place by a process of diffusion through microscopic arachnoid villi into the large dural sinuses and, to a lesser extent, through the lymph sheaths of the cranial nerves. In this spinal subarachnoid space the fluid is drained by way of the lymphatic system only. (7) Cerebro-spinal fluid circulates in the ventricles of the brain and in the subarachnoid space surrounding it. Whether it also circulates in the substance of the brain remains to be established. Movements of the fluid in the spinal subarachnoid space are probably minimal in degree.

HORLICK'S MALTED MILK

THE ORIGINAL

The Ideal All-Weather Food-Drink.

— Made in England. —

Horlick's Malted Milk is meat and drink in one, because it contains all necessary nutritive elements in the correct proportions demanded by Nature to support life and maintain health. Composed of the extracts of selected malted barley and wheat flour, combined with pure, Pasteurised cow's milk, it is perfectly digestible and rapidly assimilated, while Vitamines, those growth-promoting essentials, are supplied by both the milk and the grain.

Ready in a moment by stirring briskly in hot or cold water only.

To secure the original, specify Horlick's when prescribing

Samples will be forwarded free and postage prepaid to
Members of the Medical Profession on application to

HORLICK'S MALTED MILK CO., SLOUGH, BUCKS, ENGLAND.

THE DOCTOR'S IDEAL CAR

A new 3 seater body suitable for all chassis and specially designed to suit the especial needs of all medical men.

Cars complete with these bodies:—

Trade **'PITIBULIN'** Mark
BRAND
Post-Pituitary Extract

*Promotes contraction of the inert uterus
and, after delivery, prevents post-partum
hemorrhage.*

'Pitibulin' post-pituitary solution is physiologically tested and standardised to the highest degree of activity. Injected subcutaneously or intravenously its characteristic action is exerted directly upon involuntary muscle fibre. Thus by constriction of the peripheral arterioles it raises blood pressure, and is therefore usefully employed in shock and collapse. The action of 'Pitibulin' upon the uterine musculature comes on a few minutes after subcutaneous injection and is very marked. The degree of contraction of the isolated uterus produced by high dilutions of 'Pitibulin' is the basis of one of the physiological methods of standardisation.

Preparations.

'PITIBULIN,' 'A. & H.'

A physiologically-tested, purified extract equivalent to 20 per cent. of posterior lobe substance. Supplied in 'Azoule' form, m. 7½ (½ c.c.) and m. 15 (1 c.c.).

PITIBULIN, 'A. & H.' with ADRENIN.

'Azoule' 'Pitibulin,' m. 15, with Adrenin, gr. 200.
'Azoule' 'Pitibulin,' m. 7½, with Adrenin, gr. 100.

Sold in Boxes of 6 or 12
'Azoule' glass capsules.

DISCUSSION ON
THE TREATMENT OF NEURO-SYPHILIS.

INTRODUCTORY PAPER

BY

SIR JAMES PURVES-STEWART, K.C.M.G., C.B.,
Senior Physician to the Westminster Hospital.

PRELIMINARY CONSIDERATIONS.

BEFORE attacking the main subject of our discussion—namely, the treatment of neuro-syphilis, it is convenient to clear the ground by a few preliminary conceptions.

First, what do we mean by neuro-syphilis? Neuro-syphilis does not mean the mere presence of nervous or mental symptoms in a syphilitic patient. It comprises only such nervous or mental symptoms as are actually due to the syphilitic organism or its toxin—a totally different affair. Let me make this clear by a few simple examples. A syphilitic patient may show signs of gross organic disease of the spinal cord or brain or meninges, or he may develop mental symptoms of various sorts. These nervous or mental symptoms are sometimes of syphilitic origin—for example, gummatous disease of the brain or spinal cord, tabes dorsalis, paralytic dementia, etc. But he may also have nervous or mental symptoms quite independently of his syphilitic infection. Diseases such as hemiplegia, epilepsy, manic-depressive insanity, and dementia praecox can occur in syphilitic and in non-syphilitic patients alike.

It has long been recognized that the nervous system and its meninges may be invaded by syphilitic lesions at quite a short interval, even within a few weeks, after the original syphilitic infection. Generations ago our medical forefathers were familiar with the headaches of so-called secondary syphilis. This clinical fact they chronicled without explaining it. We now know that such headaches are the sign of a syphilitic meningitis. The old classification of syphilitic phenomena into primary, secondary, tertiary, and post-tertiary stages has had to be modified. For example, it is now recognized that gummata, which we were once taught to regard as typically "tertiary" lesions, can occur within a few weeks after infection, during the so-called "secondary" stage. Moreover, certain degenerative diseases, like tabes and paralytic dementia, which were formerly not considered as syphilitic at all, are now universally admitted as due to the disease.

In untreated cases of syphilis, even in the absence of clinical nervous or mental phenomena, Plant, Dreyfus,⁶ and others have shown that pathological changes occur in the cerebro-spinal fluid in from 80 to 85 per cent. of all "secondary" cases, coincident with the appearance of a positive Wassermann reaction in the blood. And even in cases which have been energetically treated, from 20 to 25 per cent. have pathological changes in the cerebro-spinal fluid, indicating the presence of a syphilitic meningeal reaction. Fortunately in most cases this is a transient affair, and is not necessarily followed by permanent neuro-syphilis. The high percentage of early meningeal reactions in syphilis has led some observers to the conclusion that of late years, especially since the introduction of modern methods of treatment, neuro-syphilis is becoming more frequent. I am strongly inclined, however, to agree with Fordyce and Rosen⁷ that this increase is apparent rather than real. It can be readily explained by the more accurate knowledge which we now possess of the disease, together with our more systematic examination of patients by modern methods, including especially the

examination of the cerebro-spinal fluid. Syphilitic lesions in the central nervous system also occur during later stages of the disease. These are probably due to spread from infective spirochaetal foci in lymph glands, blood vessels, peripheral nerves, and so on, reaching the central organ or its meninges along perivascular, perinoural, and periradicular lymphatics.

Discarding, then, the old classification of syphilitic lesions, according to the time of onset of the infection, into primary, secondary, tertiary, and post-tertiary (or meta-syphilitic), we prefer to adopt the pathological classification into meningo-vascular syphilis on the one hand and parenchymatous neuro-syphilis on the other, or combinations of these two.

Under meningo-vascular neuro-syphilis we include gummatous inflammations of vessel walls and of cerebral meninges, gummatous tumours, also syphilitic arteritis and peri-arteritis of the brain and meninges, together with the occasional development of secondary vascular occlusions. These morbid conditions may occur either singly, successively, or simultaneously, and at any phase of the disease.

By parenchymatous neuro-syphilis we mean a toxic, neuronc degeneration or decay, generally late in onset, exemplified in such maladies as tabes dorsalis, paralytic dementia, primary atrophy of the optic or auditory nerves, various other degenerative diseases of the spinal cord and other parts of the central nervous system.

Neuro-relapses.

The so-called neuro-relapses or "neuro-recursive" are curious outbursts of neuro-syphilis, partly meningo-vascular, partly parenchymatous. These are precipitated by certain forms of treatment, especially after insufficient treatment by arsenobenzol compounds. Drugs of this sort appear to produce their beneficial effects by dissolving the spirochaetes. But whilst so doing, and giving rise to a local inflammatory reaction in the immediate neighbourhood, a general effect may also be produced throughout the body owing to a sudden flooding of the circulation with the endotoxins of the slain spirochaetes. Such endotoxins may attack the brain or meninges, producing a neuro-relapse.

The mildest clinical variety of neuro-relapse consists in headache, vertigo, and tinnitus, often with insomnia, all of which symptoms are probably due to a basal meningitic reaction. A second variety comprises local cranial nerve lesions, especially of the optic and auditory nerves. Or still more rarely, including mental confusion, coma, epilepsy, and even death.

Such relapses are often accompanied by well-marked changes in the cerebro-spinal fluid which occur about six weeks after the last dose of a salvarsan course. They demand renewed and energetic antisyphilitic treatment.

Diagnosis of Neuro-syphilis.

What are our diagnostic criteria for the establishment of a diagnosis of neuro-syphilis? They may be clinical and neurological on the one hand (impairment of light reaction in the pupil being perhaps the commonest physical sign), or they may be serological on the other, shown by examination of the blood and cerebro-spinal fluid. These latter comprise a positive Wassermann reaction in the blood and cerebro-spinal fluid, also plocytosis of the cerebro-spinal fluid, with positive globulin and gold reactions. Better still, we may have a combination of clinical and serological signs. In order to exclude neuro-syphilis, not only must the clinical signs but also the cerebro-spinal fluid be proved negative.

It is important to remember that a normal condition of the cerebro-spinal fluid, by itself, does not necessarily exclude neuro-syphilis. As with any other physical sign, a negative observation is of less diagnostic value negatively than a positive result is positively, in establishing a diagnosis. Thus, for example, we may meet with normal cerebro-spinal fluid in many cases of syphilitic vascular disease of the brain, also in non-progressive cases of tabes and in other spinal cord degenerations of undoubted syphilitic origin. On the other hand, a patient who is clinically healthy and free from all mental disease may show well-marked changes in the cerebro-spinal fluid. Such changes may coexist with either a positive or a negative Wassermann reaction in the blood. The presence of syphilitic changes in the cerebro-spinal fluid does not always have the same significance, for whilst in most cases they indicate active syphilitic lesions of the nervous system, in other cases they may merely indicate the normal reaction of the meninges to a threatened invasion. All this shows how careful we must

be in our diagnosis before embarking upon any scheme of treatment.

Although this discussion is specially directed to neuro-syphilis and its treatment, we must never lose sight of the fact that neuro syphilis is only part of the greater subject of syphilitic infection of the body as a whole.

Preventive Treatment.

The prevention of syphilis and other venereal diseases is now the object of a great crusade by energetic rival societies. This is not the moment to open the question as to the relative merits of preventive measures locally applied before undergoing the risk of venereal infection (as advocated by one organization) versus early treatment, also locally applied, shortly after the risk has actually been incurred (as advised by the other society). Partisans of both parties may be present here, and it is not for us to enter on a discussion, however interesting, which would lead us too far from our own particular goal.

As to the special prevention of neuro-syphilis in patients who have already acquired a syphilitic infection, we must frankly recognize that, once a blood infection has occurred, there is no means by which we can fence off any particular system or organ of the body or prevent the infection from reaching all parts of the circulation, including that of the central nervous system. Our first and urgent duty, from the preventive standpoint, is to treat assiduously the general syphilitic blood infection until the patient becomes free from all clinical and serological signs. If such treatment proves successful, the nervous system will share in the general disinfection of the whole body.

Neurotropic Organisms or Syphilotropic Nervous Tissues?

It is interesting to inquire what are the factors which determine why some syphilitic patients develop neuro-syphilis, whilst others, apparently infected with equal severity and treated with equal assiduity, escape neuro-syphilis. And are any of these factors preventable?

The problem may be attacked from two different sides. Some observers argue the existence of a special strain of spirochaete which is "neurotropic"—that is, having a special affinity for the nervous tissues. In support of this view the occasional occurrence of conjugal neuro-syphilis is advanced. There is also Plant's well-known example of seven glass-blowers all of whom were infected from the same source with chancre of the lip; ten years later, out of five who came under observation, four had developed either tabes or paralytic dementia. Yet, notwithstanding experimental work on animals by Levaditi and Marie and others, the evidence of a special neurotropic strain of spirochaete is at present

is that we have to do with a variable of the nervous issues in different individuals, so that in some individuals, once they have acquired the general infection, the nervous system is specially vulnerable or "syphilotropic." Whether this supposed vulnerability is inborn or acquired is again a separate problem. Many years ago Edinger propounded his exhaustion theory, according to which it is those nerve tracts that have been specially overworked which are supposed to be picked out by the syphilitic toxin and to degenerate. In support of his thesis he pointed out the relative frequency of tabes among syphilitic individuals who specially overexerted their limbs, and the frequency of paralytic dementia amongst brain workers. Edinger therefore advised every syphilitic patient carefully to avoid physical overexertion or fatigue, so as to escape tabes, and similarly to avoid mental overstrain, so as to avoid paralytic dementia. This counsel of perfection is difficult to carry out, for who can judge exactly how much in the way of physical or mental effort constitutes overexertion?

Varieties of Syphilitic Lesions in the Central Nervous System.

We have to recognize two distinct classes of lesions.

Firstly, we have meningo-vascular lesions, including gummata and syphilitic endarteritis. Gummata arise in non-nervous tissues and compress or invade the brain or spinal cord. Diffuse gummatous infiltrations may also occur in the meninges or around the blood vessels of the brain or cord. Syphilitic endarteritis frequently culminates in thrombosis of the affected artery, producing an area of infarction or

softening in the brain or cord, followed by corresponding sclerosis.

Secondly, there is the group of parenchymatous nervous diseases, characterized by primary degeneration of various special nerve cells and nerve tracts. These diseases are neither the direct effects of gummatous deposits nor of arterial disease (although lesions of this sort frequently coexist), but they result from the direct action of the syphilitic toxin upon the nervous structures. Primary degenerative lesions of this sort may be followed by sclerotic overgrowth of the neuroglia in the affected tracts, independent of any meningeal or vascular lesion. This primary degenerative group includes such diseases as paralytic dementia, tabes, certain forms of primary optic atrophy, Erb's syphilitic paraplegia, and certain other forms of organic nervous disease occurring in the children of syphilitic parents.

These two varieties of syphilitic lesions differ widely in their respective prospects of response to treatment. Gummata, whether compressing or invading the nervous structures, can be brought to a standstill by medicinal remedies, and if the nervous structures have only been compressed and not actually destroyed recovery may be complete. If, however, a gumma leaves behind it a fibrous cicatrix, or if actual degeneration of nerve tracts has occurred within the central nervous system, a certain amount of permanent damage inevitably remains, even after the original syphilitic process has subsided. In the case of syphilitic arterial diseases, the lesion in the arterial wall may yield to treatment; but here also, if thrombosis has already occurred, producing an actual area of infarction, the damage to the structures within the territory of the diseased vessel is necessarily permanent. The prognosis, therefore, of syphilitic softenings is relatively bad. Secondly, with regard to the primarily degenerative diseases, such as tabes and paralytic dementia, these have hitherto tended to pursue an irregularly progressive course, generally uninfluenced, or at the most only slightly alleviated, by the most assiduous antisymphilitic treatment. Sometimes, however, these diseases, after attaining a certain degree of intensity, appear to come to a spontaneous standstill. Such arrest may last for years, although there is always a danger that the disease may subsequently light up again to renewed activity. We have also to bear in mind that in the case of degenerated nerve cells and nerve fibres it is only those which are outside the central nervous system, and which possess a neurilemma, that are capable of regeneration. Within the central nervous system itself, once degeneration of the nerve elements has occurred, it is vain to look for their regeneration. Therefore in parenchymatous neuro-syphilis the most we can hope for is to arrest the degeneration at the stage which it has already reached and to prevent the syphilitic toxin from attacking fresh neuronic systems.

In other words, meningo-vascular syphilis is far more amenable to treatment than parenchymatous neuro-syphilis, and the prognosis in any individual case depends not only on our actual methods of treatment but upon the relative proportions in which these two varieties of lesions are intermingled.

I have ventured to direct your attention to the foregoing points in the neuro-pathology of cerebro-spinal syphilis because it is essential in the treatment of the various types of the disease to have a clear idea of what exactly we are attacking and of how much improvement is anatomically possible, supposing the syphilitic infection be successfully removed. Let us now turn to the problem of practical therapeutics.

TREATMENT OF NEURO-SYPHILIS.

The modern treatment of neuro-syphilis does not imply that we should discard any of the older remedies which for so many years have been proved of value. The classical method of attacking syphilis is by means of mercury, supplemented in certain cases by the use of iodides. Excellent results have been obtained in the past, chiefly in the gummatous and meningo-vascular types of the disease, as every neurologist can testify. In recent years the introduction of the arsenobenzol group of drugs, of which the most notable examples are salvarsan and neo-salvarsan, has added powerful weapons to our therapeutic armoury. Most physicians agree that salvarsan produces its best results when combined with mercurial treatment.

Besides deciding in each particular case which drug or combination of drugs he will employ, the physician has also

to consider the channel of administration, whether by the mouth, by inunction or fumigation into the skin, or by injections—hypodermic, intramuscular, intravenous, or intrathecal. In making his decision the physician is influenced by various factors, such as the acuteness or chronicity of the symptoms, the amount of personal supervision that is attainable, the desirability from the patient's point of view of rendering the treatment as little conspicuous as possible (this is often a special drawback to mercurial inunction), and upon the perseverance or otherwise with which the patient, if left to himself, is likely to carry out a long course of treatment.

The present-day treatment, by a combination of salvarsan and mercury, as employed in ordinary syphilis, is applicable to neuro-syphilis as well, bearing in mind certain precautions. Thus, for example, in neuro-syphilis most of us consider it risky to give salvarsan in the full intravenous dose of 0.6 gram. It is safer to give repeated doses of not more than 0.3 gram. In this way not only do we diminish the chances of acute arsenical symptoms, but the series of smaller doses is less likely to be followed by the alarming group of intracranial syphilitic symptoms constituting the neuro-relapses to which we have already referred. Further, patients with renal or well-marked cardio-vascular disease are, as a rule, unsuitable for salvarsan medication. The very rapidity with which the drug acts in removing gummatus deposits may be a source of danger—for example, in the neighbourhood of diseased vessel walls.

Results of Treatment in Gummatus and Meningo-vascular Syphilis.

Gummatus lesions are those which respond best to ordinary antisyphilitic treatment. Time does not permit of detailing clinical examples, such as can be readily found in the experience of most of us. In a former paper I have already recorded a number of illustrative cases.

With regard to syphilitic arterial lesions within the nervous system, we are all in agreement that the amount of recovery depends on whether the syphilitic endarteritis is attacked in time, so that the lumen of the artery is restored before thrombosis has actually occurred, in which case complete recovery may be obtained. If, on the other hand, thrombosis has already occurred in the diseased vessel, leaving an infarct with destruction of nerve tissues, in this case no treatment can restore the necrosed area.

As regards the gummatus and meningo-vascular types of neuro-syphilis and their prospects of successful treatment by the ordinary antisyphilitic remedies, there seems little room for differences of opinion. The results will vary according to the stage at which such treatment is carried out.

Treatment of Parenchymatous Neuro-syphilis.

When we come to the parenchymatous group of neuro-syphilis the problem is altogether different. This group of maladies comprises primary degenerations varying in type according as the syphilitic toxin exercises its selective action upon one or other neuronic system. Thus in one case we have the exogenous fibres of the posterior columns picked out, producing tabes dorsalis; in another the lateral columns are mainly selected, as in Erb's syphilitic paraplegia; in a third we have primary optic atrophy; whilst in a fourth the cortical nerve cells with their intercommunicating tangential fibres are picked out, as in paralytic dementia. We also meet with mixed cases—as, for example, where tabes dorsalis is combined with optic atrophy, or where tabes is associated with paralytic dementia, constituting the well-known tabo-paralysis.

This class of diseases is singularly resistant to treatment, and for several reasons. First, as we have already seen, regeneration of destroyed nerve elements within the central nervous system (as contrasted with the peripheral nerves) does not occur. The most we can hope for, in the central nervous system, is to arrest the degeneration at the stage which it has already reached and to make the most of those nerve cells and fibres which survive. Another important reason for the resistance to treatment shown by parenchymatous neuro-syphilis is the peculiar situation of the syphilitic parasites with reference to the blood stream. The spirochaetes are situated in the nerve elements themselves. Now, the circulation within the central nervous system differs from that in other parts of the body, inasmuch as the capillary walls are not in contact with the nerve elements but are separated from them by perivascular lymph spaces. Moreover, each nerve cell has its pericellular lymph space. These lymph spaces are irrigated by the cerebro-spinal fluid, which

in its turn is reabsorbed into the blood through the arachnoid villi. Thus medicinal substances destined for the central nervous system have to gain access to the cerebro-spinal fluid before they can reach the nerve cells or the spirochaetes within them.

The cerebro-spinal fluid is secreted by the glandular cells covering the choroid plexuses within the cerebral ventricles. These secreting cells have a selective action, permitting comparatively few substances to pass from the blood stream into the cerebro-spinal fluid. Amongst them is alcohol, which, if administered by the mouth in sufficient quantities, can be detected in the cerebro-spinal fluid; or, again, nrotropin taken by the mouth can be shown to yield formic aldehyde in the fluid. To other substances the choroidal ependyma is impervious, notably to mercurial and arsenical salts, which at the present time are our most important spirochaeticidal drugs. Thus, no matter how assiduously the general circulation be drenched with mercury or salvarsan, the choroid plexuses do not transmit these drugs into the cerebro-spinal fluid nor allow them to reach the nerve elements. And so, whilst gummata may be removed from the meninges and interstitial tissues by remedies circulating in the blood stream, and although syphilitic endarteritis may clear up, those nerve cells and nerve fibres which are being destroyed directly by the syphilitic organism and its toxin, entrenched behind the pericellular and perivascular lymph spaces, continue to decay.

Whatever be the true explanation, it is commonly agreed that the results of treatment of parenchymatous syphilis, whether by oral, intramuscular, or intravenous routes, have been disappointing. Accordingly, neurologists have been casting around for other and more efficient methods of treatment.

Pyrexial Treatment of Neuro-syphilis and especially of Paralytic Dementia.

It has long been a matter of clinical experience that general paralytics are often benefited as regards their symptoms if they happen to become infected by an intercurrent acute fever such as erysipelas or enteric fever. To inoculate a patient with a serious specific fever of this sort, however, is neither practicable nor judicious. Other means have accordingly been suggested to induce a harmless pyrexia accompanied by leucocytosis and other blood changes, as a consequence of which it is hoped to modify and even to destroy the syphilitic organism and its toxin.

For this purpose von Wagner²² some years ago began to treat cases of paralytic dementia by repeated hypodermic injections of Koch's tuberculin, commencing with doses of 0.5 to 1 mg., waiting a couple of days, and increasing the dose to 5 or 7 mg., then gradually raising it to 10, 20, or even 30 mg. A sufficient quantity was given to induce a temperature of 102° F. Friedländer and others have recorded a number of cases thus treated and have claimed encouraging results. In several of Friedländer's cases not only did the mental systems improve, but the pupillary reflexes are said to have returned and the knee-jerks, previously absent, reappeared. Personally I have not tried this treatment, for the reason that tuberculin is a two-edged weapon with a risk of lighting up latent tuberculous lesions elsewhere.

Another method is to give the patient an intravenous inoculation of blood obtained from another individual suffering from malaria. Thus v. Jauregg, by injecting subcutaneously 1 c.c.m. of malarial blood withdrawn during the febrile phase of the disease, claims to have secured long remissions in 3 out of 9 patients with paralytic dementia.

A third and probably a safer method of inducing artificial pyrexia is by means of large intramuscular injections of sodium nucleinate, as specially studied by Donath.

Some years ago (in 1913 and 1914) I made a number of observations on this method of treatment, but with only moderately encouraging results.²³ Remissions in the mental symptoms were obtained, together with a diminution in the lymphocytosis of the cerebro-spinal fluid lasting for three to fifteen months, but in none of my six cases was there a permanent cure. Nor has Donath recorded any instance of permanent return to normal.

More recently Fischer and Wiechowski²⁴ have employed an albuminoid substance named "phlogetan." This is injected either subcutaneously or intramuscularly. They state that its action is more intense than that of nuclein, that it produces a fall of blood pressure and increase of pulse-rate, but without fever. In paralytic dementia they claim similar but more active results with this remedy than with nuclein.

In tabes treated by phlogetan combined with neo-salvarsan they record improvement, with subsidence of crises and of sphincter troubles.

Treatment by Quéry's Monkey Serum.

Quéry regards the syphilitic organism as polymorphic and the spirochaetal form as only one particular phase in its life-history. He prepares bouillon cultures from syphilitic sores and, after filtration through porcelain, injects the microbe-free syphilitic toxins into monkeys. From these in turn, four or five days later, when the Wassermann reaction in the blood has attained its height, he secures the blood serum. This monkey serum, after sterilization, is injected hypodermically into the human syphilitic patient daily in doses of 2 c.cm. for twenty-five successive days, being careful to see that an interval of at least a month has elapsed since any mercurial treatment has been employed. He also uses this same serum intravenously and, in cases of neuro-syphilis, intrathecally.

I have only had personal experience of Quéry's serum in a couple of cases; both of them gave negative results.

The first was a man of 45, with well-marked clinical signs of tabes, whose blood gave a positive Wassermann reaction and whose cerebro-spinal fluid contained 59 lymphocytes per cubic millimetre and also gave a strongly positive Wassermann reaction. After five intrathecal injections of monkey serum the physical signs were unchanged, the lymphocytosis of the cerebro-spinal fluid had risen to 77 cells per cubic millimetre, and the Wassermann reaction was strongly positive as before. In view of these findings and of the costliness of the serum, I did not feel justified in persevering with the treatment.

The second case was one of paralytic dementia in a man of 35, who had slight mental confusion, mild depression, Argyll Robertson pupils, no facial or lingual tremors, and absence of the knee-jerk and ankle-jerk on the left side only—an early case, apparently suitable for the treatment, and so considered by M. Quéry's colleague who supplied me with the serum. The patient's cerebro-spinal fluid contained 180 lymphocytes per cubic millimetre and gave a strongly positive (++++) Wassermann reaction. He was given 2 c.cm. of Quéry's serum subcutaneously twice daily. On the day before treatment was commenced the lymphocytosis had fallen to 76 cells per cubic millimetre. The treatment was then assiduously carried out daily for several weeks. A week later the cerebro-spinal fluid was re-examined; its cell content had fallen to 58.7 per cubic millimetre, whilst the Wassermann reaction was still strongly positive as before. The dementia, however, rapidly deepened, the temperature remaining subnormal, and the patient died four weeks after the commencement of treatment. The serum did not appear to exercise any appreciable benefit. On the contrary, one had the impression that the course of the disease was rather hastened. No autopsy could be obtained, the patient being of Israelitic race.

It would, however, be unfair to condemn this or any other method of treatment after so short a trial. Perhaps others here present may have had wider opportunities of using this very costly remedy (price about a guinea a dose); if so, their experience will be of value to us all.

Spinal Drainage.

Dercum¹ is of opinion that whatever good results have been attained by intraspinal therapy (which we shall presently discuss) are mainly due to the withdrawal of diseased cerebro-spinal fluid. He has accordingly introduced treatment by simple drainage of cerebro-spinal fluid, sometimes by itself, sometimes combined with intravenous salvarsan and mercurial inunctions. The patient is placed in the recumbent posture, lumbar puncture is done, and the cerebro-spinal fluid is allowed to escape all day long until some 70 or 80 c.cm. have come away. This procedure is with the object of washing out the syphilitic toxin from the cerebro-spinal subarachnoid spaces and cisternae. It does not profess to attack the spirochaetes in the brain tissue. Hoefler,¹¹ on somewhat similar lines, performs spinal drainage at the moment of intravenous salvarsan administration, in the hope that whilst the salvarsan is in the circulation as such, and before it has become decomposed into simpler arsenical salts, it may thus be induced to penetrate the nerve substance of the brain and spinal cord.

Personally as yet I have had no experience of this method of treatment, but suggestions from such a master as Dercum must always claim our respectful consideration. I therefore mention it in passing, in the hope that others here present may perhaps have had personal experience which they can pass on to us.

Intraspinal Treatment.

Many modern neurologists have adopted the plan of introducing remedies directly into the cerebro-spinal fluid. The credit of directing attention to this important principle

belongs first to Browning and Mackenzie of Glasgow (*Journal of Mental Science*, July, 1909), who proposed the treatment of general paralysis by intraspinal injection of an autogenous salvarsanized serum. Later, and independently, Marinesco¹⁵ of Bucharest in 1911, and our distinguished president of to-day, Professor George Robertson,²⁰ in 1913, actually carried out the treatment.

Subsequently Swift and Ellis²¹ of the Rockefeller Institute in New York, following Marinesco, applied the same method in cases of tabes dorsalis. Later, Ravaut¹⁸ of Paris introduced the plan of administering neo-salvarsan in minute doses directly into the cerebro-spinal fluid. Other modifications have since been tried—for example, the method of Byrnes,² who adds mercury perchloride *in vitro* to the patient's serum; or that of Ogilvie,¹⁷ who similarly adds salvarsan; or again, that of Lafora¹³ of Madrid, who adds both mercury and neo-salvarsan in suitable doses. The technique of these various intrathecal methods is more or less the same. A lumbar puncture is done in the ordinary way and the therapeutic substance is introduced through the needle, after withdrawing a certain quantity of cerebro-spinal fluid to make room for the remedy and also for purposes of control. In the intervals between the intraspinal injections the patient is assiduously treated with mercury and salvarsan.

Time does not permit of a detailed description of individual cases thus treated. Herewith I subjoin statistical tables of the results obtained in the cerebro-spinal fluid in a series of my own cases of tabes, paralytic dementia, and cerebro-spinal syphilis. These were personally observed and treated by intrathecal administration, either of the patient's own serum, salvarsanized by an antecedent intravenous injection, or of horse serum mercurialized *in vitro*.

My experience of intrathecal administration of salvarsan or neo-salvarsan directly into the spinal fluid, even in the minute doses advocated by Ravaut, is that it possesses no advantages over the other intrathecal methods. On the contrary, I have on two occasions seen it followed by a disastrous complication in the form of acute transverse lesion of the spinal cord—a result which I have never observed in cases treated by ordinary salvarsanized or mercurialized serum.

Mercurialized serum is sometimes specially useful in cases that are intolerant of arsenic, as in a patient of mine in whom salvarsan, even in the smallest dose, induced an intense exfoliative dermatitis.

Considerable difference of opinion has arisen amongst neurologists with regard to the usefulness of intraspinal therapy in neuro-syphilis. Thus, for example, Kaliski and Strauss¹² of New York condemn intraspinal therapy in paralytic dementia—a conclusion with which my own results are in agreement. But they also regard the intraspinal treatment of tabes by salvarsanized serum as of doubtful value. This is contrary to my own experience. In support of their conclusion they contend that the amount of arsenic present in salvarsanized serum is infinitesimal in amount and of no spirochaetocidal value. It seems to me, however, that they do not take into consideration the probability that it is not merely the arsenic *per se* but the antibodies which it calls forth in the blood that are the therapeutically active agents in the injected serum. Kaliski and Strauss also dispute the relative impermeability of the choroid plexus to mercury and salvarsan, and believe that remedies reach the cerebro-spinal fluid equally well whether administered intravenously or intrathecally. Roberts¹⁹ of Liverpool, however, has found no trace of arsenic in the cerebro-spinal fluid after intensive intravenous salvarsan treatment, whereas he has shown the presence of arsenic in 19 cases out of 29 one week after intrathecal injection.

Personally I have observed such encouraging results from intraspinal therapy in tabes and cerebro-spinal syphilis that I do not feel justified in discarding this method. In this conclusion I am supported by several other observers both in this country and in America. Schaller and McIntens,²¹ comparing a series of 14 cases of tabes, 11 cases of cerebro-spinal syphilis, and 1 case of paralytic dementia treated by intravenous and intramuscular therapy alone, with another series of 42 tabetics, 21 cases of cerebro-spinal syphilis, and 12 cases of paralytic dementia treated intraspinally by salvarsanized serum, are of opinion that intraspinal treatment is definitely superior to intravenous and intramuscular methods, especially in its effectiveness in clearing up the cerebro-spinal fluid: 48 per cent. of their cases became clear through the use of intraspinal methods as compared with 19 per cent. with the old intravenous method.

* Mercurialized horse serum.

My own cases corroborate the conclusions come to by Schaller and Melntens, that the most promising cases for intraspinal therapy are those of meningo-vascular neurosyphilis, that of the parenchymatous group tabetic cases are relatively the most favourable, whereas paralytic dementia and optic tabes are generally unfavourable. Cases of tabo-paralysis, in my experience, do badly, in contrast with pure tabetics.

Cases of the intraspinal serum treatment of tabes, tabo-paralysis, and paralytic dementia are recorded in Tables I, II, and III.

The following cases are illustrative of intraspinal treatment by neo-salvarsan directly into the lumbar fluid.

Case 1.—L. S. L., male, aged 44, suffering from tabes, was seen by me in February, 1914. On examination his blood gave a completely negative (---) reaction; the cerebro-spinal fluid showed 85.2 cells per cubic millimetre and a weakly positive (++) Wassermann reaction. He had been treated by neo-salvarsan. After treatment the Wassermann reaction was negative, and the cerebro-spinal fluid, remaining as before, the cell content of the cerebro-spinal fluid being 12 per cubic millimetre. After marked improvement the patient had a sudden relapse, and then gradual improvement again.

Cases of General Paralysis of the Insane.

Case 2.—R. M. S., male, aged 39. Before treatment his cerebro-spinal fluid contained 39.2 cells per cubic millimetre and the Wassermann test was strongly positive. After treatment (five injections) the cell content of the cerebro-spinal fluid was 4 and the Wassermann reaction still strongly positive. There was no change in his clinical condition.

Case 3 (Case 2 of Table III).—H. N., male, aged 42, was treated by me in March, 1914. Before treatment his blood gave a negative (---) Wassermann reaction, but his cerebro-spinal fluid was strongly positive (+++); the fluid contained 89.7 cells per cubic millimetre. After treatment (four injections) the blood remained negative, and the cerebro-spinal fluid was only weakly positive (+), the cell content being 6.9 per cubic millimetre. A week after the fourth injection of neo-salvarsan (9 mg.) he developed signs of transverse spinal cord lesion at the level of the fourth lumbar segment.

Case 4.—M. E. B., male, aged 43; seen in March, 1914. Before treatment his cerebro-spinal fluid contained 235.8 cells per cubic millimetre and the Wassermann test was strongly positive (+++). After treatment the Wassermann reaction was still strongly

10	Mrs. M. A. C.	Nov., 1919	47	+	85.0	+++	4	+	11.0	+++	Irregular pupils; spasticity of legs with ataxia	No advance in symptoms
11	G. H. B.	March, 1920	48	---	128.6	+++	7	---	12.3		Epileptiform fits	Fits much diminished.
12	W. G. E.	March, 1920	61	---	130.3	+++	6	---	12.6	+++	Spastic paraplegia	Improved.
13	R. C.	April, 1920	45	+	136.0	+++	6	-	5.3	+++	Limb pains; enuresis; left extensor reflex	Pains disappeared; bladder improved.
		Re-examined Feb., 1921		-	17.4	+	6	-	16.0	---	Eucrosis	Bladder cleared up; free from symptoms in Feb. 1921.
14	J. L.	May, 1921	47	+	18.7	+++	4	+	16.0	++-	Left hypoglossal palsy; postero-lateral sclerosis	<i>In statu quo.</i>
15	W. J.	Aug., 1921	64	++-	33.4	+++	3	+	10.0	+++	Argyll Robertson pupils; postero-lateral sclerosis	Legs improved.

positive, the cell content being 8 per cubic millimetre. Four days after the last injection the patient developed flaccid paraplegia, with absent deep jerks and flexor responses. He died three months later.

Case 5.—W. D. H., male, aged 26; seen in March, 1914. Before treatment the cell content of his cerebro-spinal fluid was 114.8 per cubic millimetre; the Wassermann test was strongly positive (+++). He received two intraspinal injections of neo-salvarsan. On examination after treatment his cerebro-spinal fluid was still strongly positive to the Wassermann test, the cell content being 47.7 per cubic millimetre. A week after the second injection he developed haemorrhagic cystitis, and died suddenly twelve days later. *Post-mortem* examination showed the kidneys and liver to be healthy; no signs of arsenical poisoning were discovered; there was old thickening of the frontal meninges.

Case 6.—B. L., male, aged 33, came for treatment in March, 1914. On examination his cerebro-spinal fluid showed a cell content of 33 per cubic millimetre, and gave a weakly positive (+) Wassermann reaction. He was given three intraspinal injections of neo-salvarsan, following which his cerebro-spinal fluid contained 40 cells per cubic millimetre, and the Wassermann reaction remained as before. He died of acute meningitis.

Intracranial Methods.

The lumbar region, although the easiest, is not the only route through which remedies may be introduced directly into the cerebro spinal fluid. Substances introduced by the lumbar route have a long distance to traverse before reaching the cranial cavity, and even then only a part of the injected fluid reaches the brain. It is therefore not surprising that intraspinal treatment is less efficient in cerebral than in spinal syphilis. Accordingly Neisser and Pollack suggested a method of cranial puncture by drilling through an area of frozen scalp, perforating the subjacent cranium, and injecting the remedy beneath the dura directly on to the surface of the brain. This has been carried out by Marinisco and Minea,¹⁶ by Sicard and Reilly,²² and others, but as a routine method it does not appeal to the ordinary clinician. Another plan is to enter the basal subarachnoid cistern through the orbit, penetrating the sphenoidal fissure with a hollow needle, as proposed by Beriel¹ of Lyons. This, however, is awkward, and includes a risk of wounding the cavernous sinus.

A more straightforward surgical procedure is to do a frank trephining operation close to the middle line of the vertex and then inject the remedy directly into one or other lateral ventricle by perforating the corpus callosum—the so-called *Balken-stich* of Anton and Brawann. This has been carried out in Germany by Förster¹⁰ and in this country by myself and by my colleague Harry Campbell,² in conjunction with Sir Charles Ballance. I have not been favourably impressed with the results thus obtained. The following personal example may be quoted:

A man of 44 came under my observation in 1919 with typical signs of early general paralysis. He was excited and delusional, but without dysarthria. There was a strongly positive (+++) Wassermann reaction in the blood and cerebro-spinal fluid, also a lymphocytosis of the fluid amounting to 104 cells per cubic millimetre. After trephining, four intraventricular injections of salvarsanized serum were given by Sir of one to two weeks. The Wassermann cerebro-spinal fluid remained unaltered, but the cell content receded to 20, 16, and then to 12 per cubic millimetre. The mental symptoms, however, continued to progress steadily, and the patient died six months later.

Intracisternal Treatment.

All the foregoing methods of reaching the intracranial subarachnoid space, with the exception of the orbital puncture of Beriel, necessitate more or less damage to the brain structures. Moreover, there is a definite risk attached to repeated cranial operations. For this reason it seems to me that the method of intracisternal puncture through the occipito-atlantoid ligament, as described by Weggeforth, Ayer, and Essick,²³ offers many advantages. Cisternal puncture, once the necessary technique has been mastered, is carried out as readily as lumbar puncture. The fluid thus introduced into the cisterna magna is carried forwards, in the current of the cerebro-spinal fluid, throughout the subarachnoid cisterns. It permeates the membranes from base to vertex, reaching every part of the cortex. Curiously enough, one finds that the amount of discomfort to the patient is less than after lumbar puncture.

The clinical results in cerebro-spinal syphilis in some cases have been striking. The following is an illustrative example of cerebral syphilis successfully treated:

The patient was a man of 43 who had typical sensory Jacksonian fits, affecting the right upper limb and right side of the tongue, together with transient dysarthria. Apart from absence of the left abdominal reflex and a somewhat indefinite plantar response in the right foot, no abnormal clinical signs were made out, whether in the cranial nerves, sensory, motor, or reflex functions. The cerebro-spinal fluid, however, contained 142.2 lymphocytes per cubic millimetre and gave a strongly positive (+++) Wassermann reaction. The Wassermann reaction in the blood was moderately positive (+/-). He was given five intracisternal injections of salvarsanized serum. The fits ceased immediately after the first injection. At the end of the series the cells had fallen to 9.7 per cubic millimetre and the Wassermann reaction was completely negative (---). The blood reaction was now feebly positive (+/-). Four months later the cerebro-spinal fluid was re-examined and contained 6.3 cells per cubic millimetre with a negative (---) Wassermann reaction. When seen twelve months after the original examination he was free from clinical abnormality, the abdominal and plantar reflexes were normal and

With regard to early paralytic dementia, I have not yet treated a sufficient number of cases by the intracisternal method to justify definite conclusions. So far, the results have been better than by any other method I have tried. In selected cases I have usually obtained a rapid remission both in the mental symptoms and in the condition of the cerebro-spinal fluid. How long such remissions will last remains to be seen. It seems to me, however, that early cases of general paralysis should at least be given a trial with this method. The cases which are most likely to benefit are patients in the earliest recognizable stage of the disease, long before they have reached the stage of certifiable insanity, whose symptoms, both mental and physical, are as yet slight, although the cerebro-spinal fluid already shows well-marked syphilitic changes.

In this connexion I may be allowed to quote the experience of Ebaugh,⁷ who employed serum salvarsanized *in vitro* and administered by the intracisternal route in a series of 28 (apparently unselected) asylum cases of what he terms the "average" type, but which we would classify as moderately advanced. In 12 of Ebaugh's cases the cerebro-spinal fluid lost its pleocytosis and its globulin reaction, but the clinical results, as might be expected in patients with advanced parenchymatous cortical changes, were disappointing, except in one instance, apparently the only patient whose malady was of short duration, in whom marked clinical improvement occurred.

Experience goes to show the importance of choosing for treatment cases of general paralysis at the earliest recognizable stage, before the onset of profound degenerative changes. Early diagnosis is an essential preliminary for hopeful treatment. No method of treatment can be expected to replace destroyed nerve elements in the central nervous organ.

CONCLUSIONS.

1. Every case of neuro-syphilis, diagnostically established by combined clinical and serological tests, demands assiduous treatment of the general syphilitic infection by every means at our disposal. Antisyphilitic remedies, including mercury, iodides, arsenobenzol, etc., are to be administered by the

most efficient route, whether by the mouth, by inunction or fumigation, by intramuscular injection, or by intravenous injection into the blood stream. In no case should our remedies be directed exclusively to the nervous system.

2. In gummatous and meningo-vascular neuro-syphilis the foregoing antisyphilitic treatment is usually all that is necessary.

3. Some cases of parenchymatous syphilis respond, but the majority are resistant, to general antisyphilitic treatment, even when carefully and thoroughly carried out. Such cases are those which should be selected for supplementary sub-arachnoid treatment, whether intrathecal or intracisternal.

4. Intraspinal treatment by salvarsanized serum prepared from the patient's own blood, or by human or horse serum mercurialized *in vitro*, is specially suitable for cases of tabes and of cerebro-spinal syphilis, provided the cerebro-spinal fluid shows evidences of active meningeal reaction. It is also suitable for meningo-vascular spinal syphilis when resistant to ordinary treatment.

5. The direct intraspinal administration of arsenobenzol into the cerebro-spinal fluid is liable to produce acute softening of the spinal cord and should be discarded.

6. Cases of general paralysis, of optic tabes, of tabo-paralysis, and of tabes with negative reactions in the cerebro-spinal fluid, are not likely to benefit by intraspinal treatment.

7. Cases of meningo-vascular cerebral syphilis benefit much by intracisternal administration of salvarsanized serum.

8. General paralysis, if recognized in the early stage, is definitely benefited by intracisternal treatment. This method is superior in efficacy to intraventricular operations and entails much less risk to the patient.

9. Pyrexial treatment of early general paralysis—for example, by tuberculin, nuclein, etc.—may induce temporary remissions in the disease. So also can simple drainage of the cerebro-spinal fluid, combined with general antisyphilitic treatment.

10. Advanced cases of general paralysis, with extensive destruction of cortical nerve elements, are hopeless for curative treatment by any method whatever.

SOME OBSERVATIONS ON THE TREATMENT
OF NEURO-SYPHILIS.

BY

S. A. KINNIER WILSON, M.A., B.Sc., M.D., F.R.C.P.,
London.

THE time is undoubtedly ripe for a pause and look round in the field of neuro-syphilis and its treatment. Immense as is the activity in this department of neurological therapeutics the question forcing itself on our attention is, "Are we getting anywhere?" Have the sixteen or seventeen years since the discovery of the spirochaete of syphilis, the twelve or fifteen since the introduction of "606" and "914," seen corresponding advances in treatment as compared with the years that preceded these epoch-marking events? I have had the curiosity to refresh my memory with a glance at the routine treatment at the National Hospital in the days of my residence there, from 1904 to 1908, and apart from the fact that some members of the staff as then constituted bravely stuck to mercurial treatment in so-called parasyphilis or metasyphilis the methods adopted were therapeutically vague and general, no doubt inevitably so. In comparison, the technique in vogue to-day has at least a pretence to vastly greater specificity, but candour compels us to admit there is still far too much of the "hit or miss" element in our treatment. I may say at once, to define my own position, that I believe we are on right lines in our efforts to reach the nervous system with therapeutic momentum, via the blood or via the cerebro spinal fluid, or both, but precision, certainty, and completeness of result are still lacking.

In our search for the causes of this imperfect state of affairs several points suggest themselves for consideration. One undoubtedly is our ignorance of the exact stages of development and intrasomatic existence of the spirochaete of syphilis. The clinician is frequently confronted with cases in which an extremely long "resting stage"—whatever it be, histologically speaking—for the *Spirochaeta pallida* must be assumed.

Thus a female patient, the subject of classical tabes dorsalis, developed symptoms at the age of 50. She had been married when 25 years old, and her husband, her equal in age, admitted syphilis at the early age of 15. Examination by the usual tests showed his nervous system to be entirely normal. Apparently, therefore, since the wife was *virgo intacta* at the time of marriage, the germ of syphilis had lived in the husband's tissues for nine years, had been communicated to the wife, presumably via the testicular fluid, and had developed into neuro-syphilis in her spinal cord no less than thirty-four years after the original male infection.

A case like this gives one furiously to think. If Wassermann tests were applied at intervals, notwithstanding the apparent health of the subjects concerned, in every case where syphilis has been contracted, however long before, I can scarcely doubt that its progress on the way to neuro-syphilis would be detected to the gain of the patient. In a regrettable majority of instances the tests are resorted to only when clinical symptoms make their appearance, which is often already too late.

A second unsatisfactory element in the treatment of neuro-syphilis resides in our inability to distinguish between symptoms due to the local presence of the spirochaete, those assignable to toxins generated by it, and those that are the outcome of structural changes developing in its train. Nowadays we do not believe—most of us, I suppose, at any rate—that either general paralysis, tabes, or tabetic optic atrophy progresses inevitably to an unfavourable issue once the degenerative process is initiated. On the contrary, there is every reason to urge that the continuance of the morbid process in these conditions is essentially due to the continuance of the activity of *Spirochaeta pallida*. No one of them has for its histological basis a primary parenchymatous degeneration of neural tissue alone, and I for one strongly object to the distinction rather in vogue at present between parenchymatous neuro-syphilis and meningo-vascular neuro-syphilis. It is notorious that in general paralysis both meningo-vascular and ependymal changes are as obvious as those of the nerve parenchyma; tabetic optic atrophy is no primary systemic neuronal disease, but is consecutive to exudative processes along the course of the nerve, derived from the pia sheath and showing themselves mainly in its intracranial and foraminal sections; and if Richter's recent work on the histogenesis of tabes is duly confirmed that disease is caused by the effects on the dorsal roots of their entanglement in granulation tissue, itself derived from the local action of the spirochaete, in the subarachnoid recess on the "radicular nerve" of Nagotte. Theoretically, were the cause removed the pathological processes involved in the

so-called parenchymatous varieties of neuro-syphilis should come to an end. Every neurologist must have had experience of two interesting groups of cases, one in which tabes, followed over a long period of years, more or less "cures itself," and another in which certain objective signs of neuro-syphilis are found in individuals who are perfectly healthy and have no complaint of a subjective kind.

As an illustration of the first of these groups I take the case of a patient with tabes, whose disease began in 1883. He attended the National Hospital in 1889, and was then extremely ill with obvious tabetic symptoms, including gross ataxia. After some years of treatment he disappeared. He turned up again in 1919, having had no treatment whatever for about twenty years, and was in every way vastly improved on his former state. On examination little else was found beyond fixed pupils and absent deep reflexes, and Wassermann tests were negative in blood and spinal fluid. The suggestion is that the tabetic process has "run itself out," presumably because the activity of the virus has died down.

To illustrate the second group I select the case of a patient who consulted me for a moderate occupation neurosis (right arm). In routine examination I found a double Argyll Robertson pupil and absent knee and Achilles jerks. Inquiry elicited the fact of the acquisition of syphilis some fifteen years previously. Tests in blood and spinal fluid proved completely negative in every respect. I can only regard the objective signs as "cicatrices" of a neuro-syphilis that, as far as the virus is concerned, is "dead."

From cases such as these the deduction is legitimate that progression of symptoms in so-called metasyphilis depends in reality on continuance of the activity of the *Spirochaeta pallida*. If, however rarely, such self-cures are attainable, we cannot allow ourselves to be beaten by neuro-syphilis. We should be able to produce similar results by our treatment from without. We may not be able to modify structural changes following the ravages of the syphilitic organism—after all, a man may go through life with absent deep reflexes or fixed pupils and be no whit the worse for it—but at least we can concentrate on what appear to be the signs of active toxicity on its part or of its actual presence in the central nervous system. In this connexion I shall cite later the case of a general paralytic in which there was good clinical evidence to suggest that some of the cardinal signs of that condition—for instance, the megalomania—are in fact the expression not of structural degeneration in the cortex but of toxic action, and the case of a tabetic where, similarly, symptoms usually regarded as structural have vanished under treatment. As is known, cases of return of knee-jerk in that disease, and of disappearance of the Argyll Robertson phenomenon, have been recorded. The truth probably is that in cases of neuro-syphilis structural deterioration does not set in as early as has been supposed, and that speedy and intensive treatment should never be hesitated over merely because there is, apparently, evidence of actual neuronal disintegration.

A third source of trouble in neuro-syphilitic treatment is commonly attributed to inaccessibility of the spirochaete in the tissue spaces of the central nervous system. I am bound to say I have never been impressed by the histological arguments adduced in support of the contention. If the spirochaete can travel in the tissues so can drugs, if in appropriate medium. Neural elements live because they are supplied with suitable pabulum via the ordinary tissue paths, and these are surely open to the conveyance of antibodies as well as of organismal products. My view of the "incurability" of general paralysis is largely that in that disease the spirochaete has started before the pistol and breaks the tape without its arsenical competitor ever having a chance of getting level with it.

Leaving these preliminary considerations, what I propose to do is to give the Section an outline of therapeutic failures and successes by the various methods I have prosecuted during the last ten years, illustrating by selected cases, and indicating the conclusions that may fairly be drawn therefrom. I shall select only the older cases which I have been able to follow up. While from time to time I have had recourse to a number of somewhat different techniques, for the sake of brevity I may state at once that the best results have been obtained with (1) mercury and salvarsan (or its substitutes) intravenously; (2) mercury, salvarsan, and salvarsanized serum intraspinally; (3) mercury and mercurialized serum, also by the intraspinal route. My experience of cisternal technique has been too recent for results to be justifiably quoted in this communication; in passing I may say that in view of the known circulation of the cerebro-spinal fluid there cannot be any material difference in effect between introduction of medicaments at one end of the cord and the same procedure at the other.

Cases of General Paralysis.

Of many cases treated during the last ten years, the following one is the solitary example of apparent success, and, as will be seen immediately, the sequel is doubtless open to adverse criticism.

The patient, a male aged 32, came under observation in June, 1915. He then presented the typical symptoms of general paralysis, more particularly those on the psychical side; he exhibited megalomania to a striking degree and "never felt better in his life"; shortly afterwards he was certified and admitted to a private asylum. Lumbar puncture revealed 265 cells per cubic millimetre, with strongly positive Wassermann and Nonne-Apel reactions. Treatment by salvarsanized serum intrathecally was forthwith commenced and continued regularly for approximately a year at fortnightly intervals. A course of mercurialized serum was substituted for it after about six or eight months. Altogether the patient received some twenty-five intrathecal injections. By the summer of 1916 he had so far recovered as to be allowed to leave the asylum, to which he never returned. The last lumbar puncture fluid examination showed only an occasional mononuclear cell; both chemical reactions were much weakened, but neither was wholly negative.

In the autumn of the same year he returned to business and made much money on the Stock Exchange. After a most successful year's work he was taken ill with chest trouble and died, according to his parents' statement, of phthisis in the autumn of 1917. To explain this it must be pointed out that the patient undoubtedly was tuberculous; he had wintered at Davos before the general paralytic symptoms developed, was known to have had a tuberculous larynx, and tubercle bacilli had been found in his sputum on several occasions.

Critical consideration of this case of general paralysis will allow the contention that the improvement was much more than merely one of the "remissions" occasionally seen in that disease, while the fact of the succession of the return to nervous health by a year's normal work in business must be admitted almost to justify the word "cure." On the other hand, when I last saw the patient, some six months before his death, he was still under the idea that the asylum sojourn was unnecessary and had in reality done him harm. Again, the concurrent tuberculosis is a very unusual feature and complicates the case to some degree; quite conceivably the tuberculous infection may have exercised a mitigating effect on the other.

The degree of success attained in this instance, gratifying as it was, is therefore somewhat qualified. It was attributed, naturally enough, to the fact that treatment was begun almost as soon as the symptoms were recognized. By way of contrast, however, I select a case also treated intensively from the outset.

The patient, a male aged 30, had had two fits, apparently typical epileptiform attacks, very shortly before coming under observation in March, 1917. As he was occupied in important work during the war these attacks—the very first symptoms—had led to his being sent for expert opinion without delay. On examination he presented slight but unmistakable signs of early general paralysis. A strongly positive Wassermann reaction in both blood and fluid, and 65 cells per cubic millimetre in the latter, with a strongly positive globulin test, completed the diagnosis.

Treatment by intrathecal mercurialized serum was commenced without delay; later it was replaced by salvarsanized serum. Altogether the patient received some twenty-eight treatments by the spinal route. He improved materially at first, but only up to a certain point. The fluid findings were very favourably modified, but the Wassermann reaction never became quite negative. An attack of gastric influenza at Christmas, 1917, pulled him back considerably, and recurrence of the epilepsy, from which he had been completely free, ensued. Treatment nevertheless was continued, but in the autumn of 1918 his friends had to send him to a private asylum, where he died about two years after I first saw him.

Here, then, is a characteristic case of general paralysis treated with assiduity from the commencement and with the patient's full co-operation, but the sequel is that of only too many instances of the affection.

I think I may say with fairness that all the cases of general paralysis I have treated, provided they are tackled at a comparatively early stage, have shown signs of unmistakable improvement at first, and up to a certain point, but thereafter perseverance in treatment has failed to effect any further change. The hopefulness of the procedure at the beginning is always belied later, with the exception of the result in the case first quoted. In spite of these disheartening features, the fact of apparent favourable modification cannot be ignored, and should provide an incentive for further therapeutic research.

Cases of Tabes Dorsalis.

From my experience of a large number of cases of this variety of neuro-syphilis, at all stages, my considered opinion is that persistent intravenous and intraspinal treatment has

justified its adoption as a routine method. Among various impressive cases the following may be chosen for illustration:

A woman, aged 50, had the characteristic subjective symptoms of tabes for about twelve months before coming under care in May, 1916, when, on examination, the classical picture of the disease was found—in particular, marked ataxia, rectal incontinence, severe shooting pains, absent deep reflexes, fixed pupils, loss of deep pressure-pain in the legs, and so on. In the blood the Wassermann test was negative; in the fluid a strongly positive globulin reaction, a weakly positive Wassermann, and 30 cells per cubic millimetre indicated the nature of the affection conclusively.

Treatment with mercurialized serum intrathecally was forthwith inaugurated, and this was replaced later by salvarsanized serum. In all, some sixteen injections were thus administered in the course of about eighteen months. The result was eminently satisfactory. Clinically, the pains vanished, the rectal incontinence ceased and never returned, and the ataxia was reduced to a negligible element in the case. At the end of the treatment the cells were less than 5 per cubic millimetre, the Nonne-Apel test was negative, and the Wassermann test was on the margin of negativity. The patient was seen and re-examined some two and a half years later, and the improvement was fully maintained, though, naturally enough perhaps, the pupils remained fixed and the deep reflexes were still absent. A still later report (July, 1922) informs me that the patient enjoys good health and full bodily activity, and is "better than she has been for years."

Special attention may be directed to the fact that in this case symptoms commonly held to be of structural origin—namely, the rectal incontinence—disappeared as the result of treatment and did not recur. Another example of the favourable modification of symptoms of this class—namely, bladder crises and incontinence—is the following:

A male patient, aged 39, came under care in June, 1916. He had contracted syphilis twelve years previously, and on examination exhibited evidence of tabes dorsalis in the form of typical shooting pains, loss of bladder control, loss of sexual desire and power, ataxia and anaesthesia in the limbs, Rombergism, double Argyll Robertson pupil, and absence of all deep reflexes. The Wassermann reaction was strongly positive, both in serum and fluid. In the course of some two years the patient was given ten injections of mercurialized serum intraspinally, and twelve of novarscnobenzol intravenously. Again, in 1920-21 intravenous and intrathecal treatment was repeated. As a result, the patient has been able to resume his occupation in the marine profession, and at present (June, 1922) has proceeded in the course of his duties on a voyage to the West Indies.

The bladder incontinence and crises have been overcome; the pains are entirely negligible; the ataxia is scarcely noticeable; and sexual desire and power have greatly improved. On the other hand, a fall some six months ago has resulted in what appears to be an incipient Charcot arthropathy of the right tarsus. The pupils and deep reflexes remain as before.

As a contrast to these and similar cases that might be cited we may, for a corrective to too optimistic a purview, glance at the following tabetic history:

A male patient, aged about 45, who had contracted syphilis twenty years before, was found on examination in March, 1918, to show all the usual symptoms and signs of advancing tabes dorsalis. He was thin and pale, and looked like a man who had been through a long and arduous life.

Looking on the case as eminently one for intensive treatment, and persuaded by the comparative mildness of the various tests and reactions that the outcome would be favourable, I initiated treatment, on this occasion with galvanized serum intraspinally. During thirteen months some eight injections were administered; later, treatment was continued with intravenous arsenic only, and later still intrathecal medication was again resumed. The clinical improvement of the first nine months was not maintained, and while the cells were reduced to a normal level the globulin and Wassermann tests never became less than "slight," though I expected them certainly to become negative. In the course of the next year the patient's condition gradually became worse, in spite of his own medical attendant's perseverance with intravenous arsenic, and some two years after his coming under observation he died.

I must own to disappointment in this latter case, nor is that tempered by exact knowledge of the reasons for the failure. On the face of it, it appeared more suitable for treatment than many others which have been handled with better result. I can only suppose the methods were not pushed sufficiently; through unavoidable circumstances the injections were given somewhat irregularly, and not in the total amount of some of the others here quoted. Nevertheless in this instance an apparently favourable case did not respond to treatment in any material degree.

My experience in cases of tabetic optic atrophy has been uniformly disappointing, here let it be said. Its treatment is an unsolved problem, for we should get better results than we do.

Cases of Cerebro-spinal Syphilis.

There appears to be a consensus of opinion as to the suitability for and responsiveness to treatment of cases of neuro-syphilis, cerebral or spinal, not belonging to the categories of tabes and general paralysis. The meningo-vascular form, however, has always been more responsive to mercury and iodides than the others, so that the question for the moment is, Has our control over its manifestations been enlarged or strengthened by the adoption of the newer methods with intravenous or intraspinal arsenic? On the whole, and in spite of numerous satisfactory results which might be used in illustration, I cannot say that I am entirely convinced it has. In opposition to what seems, at least to me, to be the usual contention in recent years, I believe that the addition of the arsenical preparations to our antisyphilitic armamentarium has, as far as neuro-syphilis is concerned, proved as great a help in tabes as in cerebro-spinal syphilis, if not indeed greater. In other words, the coupling of arsenic with the well-tried mercury and iodide methods has influenced tabes more than it has the other, in which the latter technique has never really lost caste, so to speak. Be this as it may, just as with the other varieties I am able to quote satisfactory and unsatisfactory instances alike.

It is scarcely necessary to furnish examples of successful treatment of ordinary syphilitic hemiplegia, paraplegia, etc., and of somewhat rarer manifestations, such as syphilitic sciatica, syphilitic amyotrophy, and so on. Routine treatment in all such types of case with the time-honoured mercury and iodides seldom fails to effect material improvement, and the addition of intravenous arsenic is no doubt advisable, but intrathecal medication also has its place in selected instances.

The most striking example of the value of the newer treatment that occurs to me is furnished by a case of meningitis syphilitica acutissima. The patient, a male aged 24, had contracted syphilis in 1918, and some three months later developed sudden symptoms of meningitis, so acute and extreme in degree as at once to lead to a clinical diagnosis of cerebro-spinal syphilis. This was apparently confirmed by the meningococci were found, the cell exudate being predominantly polymorphonuclear, with a moderate amount of mononuclears, chiefly medium and small. A week later it became clear that cerebro-spinal fever could be excluded, and that the case was one of generalized syphilitic meningitis of the acutest variety. A strongly positive Wassermann reaction was obtained in both blood and cerebro-spinal fluid. Mercurial inunction and six intrathecal injections of mercurialized serum effected a marvellous change, and from being at death's door the patient made an uninterrupted recovery. In three months the spinal fluid was completely normal in all respects. Three years later the blood and fluid were again entirely normal.

I do not hesitate to affirm that this case of acute syphilitic meningitis owed recovery to the immediate instillation of antisyphilitic remedies into the subarachnoid space and that no other technique would have served so well. Where there is histological evidence of meningeal irritation by the syphilitic virus in cases of cerebro-spinal syphilis intrathecal medication should be added without fail to mercurial and iodide methods.

On the other hand, some cases of the meningo-vascular kind fail to respond, in spite of every effort.

Thus a male patient, aged 47, of unknown date previously, came of a left external rectus paresis, reaction was very strongly positive examination no other objective signs were present. Year after year patient treatment with mercury, iodide, and intravenous arsenic was prosecuted. Altogether some thirty-five or forty intravenous injections of galyol, kharsivan, and novarsenobenzol were administered. Yet no clinical improvement was obtained; on the contrary, the ocular condition spread, cardio-vascular degeneration ensued, and the Wassermann reaction in the serum remained disappointingly positive. Rather less than one year ago the patient died from the cardiac condition.

General Conclusions.

In the treatment of all varieties of neuro-syphilis distinction must be drawn between toxic and structural or degenerative symptoms—that is, as far as such distinction is in the present state of knowledge practicable. As yet we have no certain means of detecting spirochaetal activity except by serum and spinal fluid tests, so that their positivity or otherwise remains the criterion (scientifically a little debatable if useful practically) by which to judge whether treatment should be further prosecuted or not. At the same time, one can never afford to ignore clinical evidence. Like many other investigators, I have found improvement in cell and globulin tests to precede change in the Wassermann test, and I have not a

little evidence which goes to prove that noteworthy clinical amelioration may be accomplished notwithstanding a persistently positive Wassermann reaction. It thus becomes a practical question whether the latter is an unfailing index to the actual pathological condition. On the whole, I make it a working rule at present always to aim at complete reaction—negativity, but in not a few instances where marked improvement has been brought about—for example, in cases of tabes—intrathecal or intravenous treatment has been broken off before such aim has been reached, and not, I have found, with any particular disadvantage. Nevertheless it is abundantly obvious that treatment has to be persevered with over long periods, or repeated at more or less regular intervals in courses, if any enduring result is to be achieved.

Within the last few years I have experimented on a fairly wide scale, in cases of so-called parenchymatous neuro-syphilis, with arsenic by the intravenous route only, examining the spinal fluid at intervals to ascertain whether any improvement therein can be thus attained. In several cases such improvement has been procured, yet on the whole the clinical results have been better with intrathecal treatment than without it. I am bound to say further that with mercurialized serum my results have been superior to those obtained by salvarsanized serum. The disadvantage of the former is the pain to which its injection frequently gives rise, apart from the scientific objection that its constitution is not the ideal one for the purpose. The profession still awaits the introduction of a soluble form of mercury which can be administered via the spinal route with a minimum of disturbance and a maximum of efficaciousness. In my opinion such a preparation will prove superior to any form of arsenic.

In judging of the value of any particular form of treatment the clinician must never forget to discriminate between transient and permanent symptoms, as already hinted. A patient with spastic paraplegia from syphilitic meningo-myelitis may under treatment have his serum and fluid tests changed from positive to negative and still be handicapped by his spasticity. Lateral sclerosis once established will persist, as far as we know at present—a cicatrix of dead tissue in the spinal cord. It is obviously unfair to decry special treatment though the results of the disease remain; as well might we refuse to consider removal of a spinal tumour a success because its pressure has caused a degeneration which no surgeon can alter. The moral, of course, is abundantly plain: the earlier and more intensive the treatment in any form of neuro-syphilis the more hopeful is the prognosis.

This question of structural changes calls for more consideration than I am able to give it within the limits of this paper. I may in conclusion, however, be allowed to say that the treatment of gummata in the nervous system is something quite special. In brain or cord a gumma is to all intents and purposes a foreign body, a tumour. Antisyphilitic remedies affect its structure so little as to be valueless. Where localizing symptoms have pointed to a circumscribed gumma, say meningo-cortical, I have always counselled its removal by surgical means, and some of the most striking cases I have had of success in cerebral tumours have been in those whose tumour has proved to be a gumma. In the spinal cord, similarly, if one could only be sure clinically that the symptoms of transverso lesion were referable to a gumma and not merely to a meningo-myelitic infiltration or softening, I should unhesitatingly advise operation.

THE TREATMENT OF NEURO-SYPHILIS, WITH SPECIAL REFERENCE TO THE CHANGES IN THE CEREBRO-SPINAL FLUID.

BY

DOUGLAS K. ADAMS, M.A., B.Sc., M.D.,
Glasgow.

In the course of an investigation into the etiology and treatment of disseminated sclerosis on behalf of the Medical Research Council it was decided to investigate by way of control a wide series of cases of various nervous diseases with special reference to neuro-syphilis. The work has been done in collaboration with Dr. Ernest M. Dunlop and Dr. Wilfrid Scott, the pathological portion of the investigation being carried out in the pathological laboratories of the University and Western Infirmary of Glasgow.

Cases of neuro-syphilis which may be grouped as follows have been subjected to investigation and antisyphilitic treatment: tabes dorsalis, tabo-paresis, general paralysis of the

insane, Erb's syphilitic spinal sclerosis, motor neurone disease, and meningo-vascular syphilis. It must, however, be observed that such a classification is based on purely anatomical and clinical considerations, and that modern research tends to emphasize that all possess the same basis—namely, a pathological condition of the nervous tissue or its coverings due to the presence of the *Spirochaeta pallida*. The point of attack presumably is determined by other factors.

It is of interest that in 12 out of a total of 17 cases of syphilitic spinal sclerosis, the diagnosis depending upon clinical indications of involvement of the motor tracts associated with a positive Wassermann reaction in either the blood or cerebro-spinal fluid or both, the cell count was within normal limits—that is, these cases did not show the pleocytosis which is so constant in neuro-syphilis. In this respect the cerebro-spinal fluid picture approximates more closely to that found in disseminated sclerosis, a disease which syphilitic spinal sclerosis may so closely simulate that the differential diagnosis in some cases depends solely upon the Wassermann reaction unless the coexistence of the two diseases be conceded.

With regard to treatment, as we are dealing with an active spirochaetosis, there is the strongest possible indication for the administration of antisyphilitic drugs. It is therefore logical to consider the following questions: (1) Do the therapeutic substances administered reach the infective focus? (2) Is the administration of such drugs attended by risk or ill result? (3) Does serological improvement follow? (4) Is clinical improvement obtained?

As regards the first question, although the results of various observers have been contradictory, there is a certain amount of evidence that arsenic does reach the infective focus, though whether in a sufficient degree of concentration is not altogether clear. Hall, Callender, and Holmblad¹ state that arsphenamin given intravenously in 0.6 gram doses may be detected in 25 to 35 per cent. of the cases. More recently Mehrkens and MacArthur² have demonstrated that when spinal drainage by means of lumbar puncture follows the intravenous administration of arsphenamin there is no increase of arsenic penetration, though they report a high rise in positive results when meningeal irritation by means of an intraspinal injection of the patient's own serum has previously been carried out. Corbus, O'Connor, Lincoln, and Gardner³ claim that the amount of arsenic entering the cerebro-spinal fluid is increased by the previous intravenous administration of hypertonic saline solution, and after this procedure they found arsenic in the cerebro-spinal fluid in 93 per cent. of cases, the amount varying from a trace to 0.01 mg. per cubic centimetre. It has also been shown by Osborne⁴ and other workers that iodine can be detected in the cerebro-spinal fluid following on the administration of iodides, and there is evidence to show that the amount so found is greater when the salt has been given intravenously than is the case after oral administration. These facts are of prime importance, as they prove that the chief therapeutic agents do penetrate into the cerebro-spinal fluid, a fact which has frequently been denied.

Along with Dr. Browning and Miss Gulbransen an attempt was made to demonstrate the presence of therapeutically active arsenic in the cerebro-spinal fluid by the following means: The patient received 0.6 gram novarsenobenzol intravenously, the cerebro-spinal fluid was drawn off twenty-four hours later, a mixture of the fluid with blood containing active *Trypanosoma brucei* was incubated for from ten to twenty minutes and then injected into mice. No definite retardation of the resulting infection could be determined even when the animal received subsequently a further injection of the fluid when the trypanosomes appeared in the blood. Of course, this negative result cannot be interpreted as excluding the possibility that in the patient arsenic reaches the central nervous system in a form and amount adequate to produce chemiotherapeutic effect.

In the second place, as regards possible risk or ill result, in the course of this investigation upwards of 2,000 injections of novarsenobenzol have been administered to about 200 cases. No fatal case has been recorded: in two instances mild jaundice developed after the salvarsan administration, but it has to be noted that two similar cases of jaundice occurred in two patients suffering from neuro-syphilis before any salvarsan treatment had been given. In two cases slight arsenical dermatitis occurred; these cleared up immediately following the administration of intramine. The so-called Herxheimer-Jarisch phenomenon has never been observed in this series. In the past its importance appears to have been

exaggerated, and it seems probable that a previous course of mercury and iodide will prevent its onset. Numerous cases showing slight optic atrophy have been subjected to intensive treatment and no ill effect noted on subsequent examinations. Optic atrophy is still regarded by some as a contraindication to the administration of salvarsan. This is apparently due to the fact that the administration of atoxyl, which represents a stage in the synthesis of drugs of the salvarsan group, led to a number of cases of permanent blindness. As Browning⁵ has recently stated, the chemical side of the relationship between the two substances is of about the same degree of closeness as that of alcohol to sugar. In no case treated in this series has ill effect been recorded, and in no case has any result been obtained to justify the opinion that the treatment of neuro-syphilis is in any way more dangerous than that of primary syphilis.

As regards the question of serological improvement, the results obtained in the treatment of fully established cases of neuro-syphilis show a constant and progressive fall in the cell count until this reaches normal limits, almost constant modification of the colloidal gold reaction in the direction of a negative result, and, in occasional cases, a change in the Wassermann reaction from positive to negative. As examples of this the following observations are tabulated below:

Case 70.—J. G., aged 31, contracted syphilis in 1906. Treated with mercury for six months. Condition on May 17th, 1920: Pupils unequal and did not react, complete left third nerve paralysis, paralysis of right external rectus. K.J. + +, no ankle clonus, plantar reflexes flexor.

Date.	Blood: Wassermann Reaction.	Cerebro-spinal Fluid.			
		W.R.	Cells.	Protein.	Colloidal Gold.
May 17, 1920	Suspicious	Positive	42	Excessive	1135210000
Sept. 29, 1920	Positive	Positive	7	Normal	1111300000
Oct. 30, 1920	—	Positive	2	Normal	1111000000
Dec. 5, 1920	Suspicious	Negative	3	Normal	1111000000

Case 22.—J. McI. Tabes dorsalis. Argyll Robertson pupils, optic atrophy, absent knee-jerks. Rombergism and ataxia.

Date.	Blood: Wassermann Reaction.	Cerebro-spinal Fluid.			
		W.R.	Cells.	Protein.	Colloidal Gold.
Mar. 19, 1920	Weak positive	Positive	44	Excessive	5555431000
May 25, 1920	Negative	—	—	—	—
July 20, 1920	Negative	Positive	70	Excessive	1244420000
Oct. 29, 1920	—	Positive	11	Normal	2333310000
Jan. 28, 1921	Negative	Positive	6	Normal	2332100000
Dec. 14, 1921	Negative	Unsatisfactory	—	—	—
April 26, 1922	Negative	Negative	0	Normal	2211000000

Case 72.—S. M. Neuro-syphilis. Admitted May 20th, 1920, complaining of loss of power in both legs and arms, adder and bowels of eight months' duration, vision slightly to light. Exophthalmos, normal. Slight intention tremor. Legs spastic with loss of power. Ankle reflexes of legs + +. Ankle clonus, plantar reflexes extensor.

Date.	Blood: Wassermann Reaction.	Cerebro-spinal Fluid.			
		W.R.	Cells.	Protein.	Colloidal Gold.
May 20, 1920	Positive	Positive	100	Normal	2244211000
Oct. 2, 1920	Positive	Negative	30	Normal	0122100000
Nov. 20, 1920	Weak positive	Negative	3	Normal	3222100000
Feb. 5, 1921	Weak positive	Negative	4	Normal	0111000000

As regards the clinical improvement obtained in the treatment of established cases of neuro-syphilis it must be borne in mind that nervous tissue has minimal power of regeneration and consequently, once definite damage has been done, return to normal function is impossible, though, even in such cases, treatment may arrest the further progress of the

disease at the stage at which it is first encountered. In the cases treated in this series improvement as regards gait, bladder control, lightning pains, and general health has repeatedly been observed, though the lapse of time is not yet sufficient to warrant the conclusion that the disease has been arrested. The whole hope of the successful treatment of tabes and other forms of neuro-syphilis lies in early diagnosis. If the disease can be recognized in the stage of symptoms rather than that of signs a return to normal function may be hoped for, a symptom being regarded as a manifestation of disordered function having no underlying structural change of an irreversible kind. During the progress of this investigation special attention has been devoted to cases pres of early involvement of the ner following case is an example of this :

W. C., aged 24, reported to Dr. Brownlow Riddell at the Glasgow Eye Infirmary on November 22nd, 1921, complaining of double vision which had originated the previous day. Dr. Riddell reported that the diplopia was apparently due to paresis of the right superior rectus muscle. On the 24th there was definite involvement of the right external rectus with crossed diplopia, and no longer double vision in the upper part of the field. On November 30th the eye symptoms had completely cleared up, and a thorough clinical examination of his nervous system revealed no abnormality whatever.

The serological findings in this case were: Wassermann reaction of blood, positive; cerebro-spinal fluid: Wassermann reaction, negative; cells, 3 per cubic millimetre; protein content not increased; colloidal gold reaction, 44443311000.

It is desired to emphasize that in this case transient diplopia was at the time the only clinical evidence of nervous disease, but that as the result of serological investigation a definite diagnosis was established at a stage when cure by treatment might be hoped for.

The symptomatology of onset of these diseases is frequently disregarded or cautiously interpreted, but the correlation of such symptomatology with definitely altered serological reactions may enable the early diagnosis of diseases of the nervous system to be placed on a much more definite etiological basis, and therefore open the way for vigorous specific treatment at a stage at which complete recovery of function is possible.

Technique of Treatment.

The routine adopted in the series of cases here referred to has been a preliminary course of mercury and iodide for an average of two weeks, followed by a series of from twenty to forty injections of 0.45 to 0.6 gram novarsenobenzol given at seven-day intervals. After every fourth injection two weeks' rest was given. Prior to each injection there was no elaborate preparation with starvation, the only departure from the ordinary routine being a saline aperient and slight curtailment of breakfast on the morning of the injection. In addition, mercurial inunction according to the Aachen methods was carried out and intramuscular injections of intramine in 5 c.cm. doses were given at monthly intervals. Perhaps to the latter fact the freedom from ill result may be in part attributed, and in some cases the intramine appeared to intensify the serological improvement obtained. Recently the effect of more frequent administration of smaller doses of novarsenobenzol has been tried in view of statements regarding the rapid excretion of arsenic from the cerebro-spinal fluid, but no statement can be made regarding the special effects of this procedure.

No intrathecal therapy has been attempted, and silver salvarsan has not been employed.

Tabes and other forms of neuro-syphilis have been recognized as clinical entities for generations and we have inherited a wealth of information from the older writers in days when modern serology and bacteriology were unknown and the causal organism unsuspected. All such writers emphasize the necessity of a well-ordered life, the abstinence from stress and strain, and above all the protection from injury in the treatment of these cases. Spontaneous arrest, presumably due to the fact that the syphilitic infection has "burned itself out," may and often does occur, and it is not improbable that the chief factor in its production is the ordering of life along the smoothest possible channels. Under such conditions *vis medicatrix naturae*, on which all healing ultimately depends, may result in arrest, but with our later knowledge of the infecting organism and of the specificity of the salvarsan molecule for the *Spirochaeta pallida* the application of these modern methods may, and in many cases does, supply the

help that is needed in the struggle of the tissues with the infecting organism and so shift the balance in the patient's favour.

THE WASSERMANN REACTION IN THE DIAGNOSIS AND CONTROL OF TREATMENT OF NEURO-SYPHILIS.

BY

ERNEST M. DUNLOP, M.C., M.B., Ch.B.,

Glasgow.

THERE has been an opportunity recently in this department of testing the Wassermann reaction of the bloods and cerebro-spinal fluids of a considerable number of cases of neuro-syphilis and other nervous diseases, and the results of these tests are summarized in the present communication.

In addition to the examinations that have been carried out in conjunction with Dr. Douglas K. Adams two further series of tests, made during the same period, are included in this summary. The first of these represents the bloods from probable or suspected cases of tabes dorsalis and general paralysis of the insane and all cerebro-spinal fluids which have been submitted from the wards or out-patient department for Wassermann test. The second series consists of examinations of the cerebro-spinal fluid of 94 cases of clinical syphilis attending the Venereal Diseases Centre, who had already received energetic antisyphilitic treatment and the Wassermann reaction of whose blood was no longer positive.

In all cases the method of testing the Wassermann reaction has been as detailed by Browning and Watson,¹ and the criterion of positivity adopted that of Browning and Keenaway,² who emphasize the distinction between a diagnostic and a therapeutic positive in the interpretation of results.

For purposes of classification the cases may be divided into:

- A. Tabes dorsalis, or suspected tabes.
B. General paralysis of the insane, or suspected general paralysis of the insane.

- C. Miscellaneous, presenting a variety of clinical pictures.

In this last group are included the cases with clinical manifestations of disseminated sclerosis in whom a positive Wassermann reaction was obtained in the blood, cerebro-spinal fluid, or both, and which are referred to by Dr. Adams as syphilitic spinal sclerosis.

(A) Wassermann Reaction in Tabes Dorsalis (107 Cases).

Specimen.	No. of Cases.	Wassermann Reaction.			Negative Results.
		Positive.	Suspicious.	Negative.	
Blood...	99	66	3	30*	30%
C.S.F. ...	70	48	1	21	30%
Blood and C.S.F.	62	35 (in both) 8 (blood only) 8 (C.S.F. only)	1†	10 (in both)	16%

* Two of these cases developed a positive reaction during the course of treatment.

† One of the two cases whose blood Wassermann reaction became positive during treatment.

In the series in which both blood and cerebro-spinal fluid were examined a positive reaction was obtained in one or both in 51 of the 62 cases (that is, in 82 per cent.), while in only 10 of the cases was it negative in both (16 per cent.). It will be noted also that at the original test in one of the cases the cerebro-spinal fluid gave a suspicious reaction and the blood a negative. During treatment, however, this blood was examined twice again, when the results were (a) suspicious and (b) weak positive. Of interest, too, is the fact that, but for the examination of the cerebro-spinal fluid, a positive reaction would have been missed in 8 of these patients, a point to which attention has already been drawn by numerous observers.

* From the Pathological Department of the University and Western Infirmary of Glasgow. This work was done with the support of the Medical Research Council.

(B) Wassermann Reaction in General Paralysis (22 Cases).

Specimen.	No. of Cases.	Wassermann Reaction.		Negative Results.
		Positive.	Negative.	
Blood	19	12	7	37%
C.S.F.	12	10	2	17%
Blood and C.S.F.	9	7 (in both)	2 (in both)	22%

From the clinical data furnished with these cases it would appear that in several instances the Wassermann reaction was tested, not to confirm a diagnosis of general paralysis of the insane, but rather in order to rule it out of count.

(C) Wassermann Reaction of Cerebro-spinal Fluid in Miscellaneous Cases (330).

In this series the great majority of the cases presented signs or symptoms of nervous disturbance, but, by way of control, a number were included whose disabilities fell under such headings as: anaemia, pernicious anaemia, diabetes, gastritis, aneurysm, myxoedema, valvular disease of the heart, trench-feet, intermittent hydrarthrosis, rheumatism, carcinoma of stomach, arterio-sclerosis, enlarged prostate, spondylitis deformans.

Among the nervous cases the following conditions were represented: disseminated sclerosis, amyotrophic lateral sclerosis, epilepsy, paraplegia (spastic and ataxic), coma or lethargy, tumour (brain), optic atrophy, diplopia, myelitis, various pareses, hemiplegia, Raynaud's disease, insomnia with choreic movements, Parkinson's disease, delusional insanity, mental deficiency, meningitis, exophthalmic goitre.

The Wassermann reaction was positive in 46 of the 330 cerebro-spinal fluids tested, and, excluding 6 whose clinical summaries have not been traced, the disabilities of these patients were as follows:

	No. of Cases.
Spinal sclerosis	23
Meningo-vascular syphilis	4
Hemiplegia (a)	2
Cerebro-spinal syphilis	1
Argyll Robertson pupil and headache (b)	1
Argyll Robertson pupil and nephritis (b)	1
Epilepsy	1
Lethargy (c)	1
Exophthalmic goitre	1
Anasarca (d)	1
Meningitis or meningismus (e)	2
Functional (?)	2

(a) Wassermann reaction of the bloods also positive.

(b) In these two cases further indications of disorder of the nervous system are lacking in the available clinical summaries. In each case the Wassermann reaction of the blood was positive.

(c) Patient, a boy, aged 16, whose intelligence was low and who, for a year, had been lethargic during the daytime.

(d) Patient, an engine-driver, aged 52; no abnormality found clinically in the urine or in the fundi oculorum. Temperature normal. Leucocytes 22,500 per cubic millimetre. Wassermann reaction of blood negative.

(e) In these two cases further tests were not obtainable. In each the Wassermann reaction of the cerebro-spinal fluid was weakly positive.

In 24 of the above cases the Wassermann reaction of the blood was tested also and in 7 of these it was negative. (In the 7 cases series similar differences in the reactions have been already noted.)

Wassermann Reaction in Cerebro-spinal Fluid of 94 Cases of Treated Syphilis.

In the examination of the Wassermann reaction of the cerebro-spinal fluids of 94 cases of treated syphilis from the Venereal Diseases Centre whose blood Wassermann reaction was negative, the following results were obtained: Wassermann reaction of cerebro spinal fluid: positive 6, negative 88. Of the six positive cases only one had recognized signs or symptoms of nervous disability (hemiplegia), and in these cases antisymphilitic treatment had been commenced as follows:

In the primary stage	2
While on service (? primary)	1
In the tertiary stage (hemiplegic referred to above)	1
On account of positive Wassermann reaction in blood	1
On account of miscarriages (Wassermann reaction in blood originally positive)	1

Of the 88 negative cases 6 presented evidence of nervous disturbance. In three of these, however, this amounted only to headache; in one to headache and failing vision; in one to dizziness; while in the last there were definite signs of bulbar involvement. Treatment had been commenced in these cases as follows:

Primary stage	17
Secondary stage	31
Tertiary stage	19
Nervous	1
On account of a positive Wassermann reaction in blood	7
While on service (? primary)	5
Cases in which the clinical summaries at the beginning of treatment were not available	8

The majority, if not actually all, of the cases who received treatment on account of a positive Wassermann reaction in the blood had had their bloods examined as a result of syphilis in their consorts or their children.

Therapeutic Effect on Wassermann Reaction in Neuro-syphilis.

The Wassermann reaction of the cerebro-spinal fluid has been followed during the course of treatment in 26 cases of neuro-syphilis, and in 5 of these a modification of the reaction has been noted. In two of these, cases of tabes, the reaction in the cerebro-spinal fluid, originally repeatedly positive, became negative after seven months' treatment in one instance and after twenty-four months in the other. The remaining three cases were diagnosed syphilitic spinal sclerosis, and in two of these the Wassermann reaction of the cerebro-spinal fluid changed from positive to negative after four and four and a half months' treatment respectively. In the last case, also positive originally, a suspicious reaction only was obtained at the end of four months' treatment.

In the case of the blood the Wassermann reaction has been studied in a series of 23 cases of neuro-syphilis undergoing treatment, and, in addition to the two "provoked" reactions referred to previously, a modification has been noted in six of these. In one, a case of syphilitic spinal sclerosis, the reaction changed from positive to negative after four months' treatment. The remaining five cases were suffering from tabes, and in four of these the reaction altered from positive to negative after from two and a half to eleven months' treatment. In the last it changed from positive to suspicious after eleven months.

In the other 21 cerebro-spinal fluids and 16 bloods no modification occurred in the course of observations lasting over periods of from four to nineteen months.

"Provoked" Type of Wassermann Reaction.

In two instances referred to above, both clinically cases of tabes, the Wassermann reaction of the blood, originally negative, became positive after the commencement of treatment. In one of these the change occurred within a week of the first intravenous dose of novarsenobillon, while in the second a definitely positive reaction was not noted until five months later. The first corresponds to the so-called "provoked" positive reaction, of which one similar case has come to the notice of the author in a series of 36 treated syphilis attending the Venereal Diseases Centre. The second is of the type described by Strickler, Manson, and Sidlick, who indicated that out of 24 dermatological cases examined by them whose blood Wassermann reaction was negative and who were almost certainly non-syphilitic, a large number, 66 per cent., developed a positive reaction at some period during the course of an experimental intravenous arsenical treatment, arsphenamin being the compound employed. In view of the importance of this observation, could it be confirmed, it was arranged to carry out regular examinations of the Wassermann reaction of the blood in a series of patients, free from serological evidence of syphilitic infection, who were having weekly doses of novarsenobillon, 0.6 gram, intravenously. Ten such cases were investigated, and the number of examinations in each ranged from four to seven:

7 weekly tests	3 cases.
6 " "	2 " "
5 " "	2 " "
4 " "	2 " "

In every case a sample of blood for a Wassermann test was withdrawn immediately before the administration of the dose of novarsenobillon, and the first specimen of blood was taken before any intravenous arsenical treatment had been given.

In only one of the ten cases—one already noted—was any marked change in the Wassermann reaction obtained. In this case—clinically tabes—the reaction became positive after the first injection, and it remained so during the following two and a half months, when regular Wassermann tests of his blood were being carried out. In one other case, clinically suggestive of tabes, a doubtful negative reaction occurred during the eighth and ninth weeks after treatment commenced. The results before and after this period were uniformly negative.

In addition, one of those in the laboratory here, whose serum has been used frequently as the negative control for the Wassermann tests, had three injections of novarsenobillon (0.3, 0.45, 0.45 gram) administered intravenously, at weekly intervals, during August last. The Wassermann reaction of his blood immediately before the first dose, and at weekly intervals for four weeks thereafter, was tested, and on all of these occasions it was uniformly negative.

In view of these findings it would appear that there is no evidence of the intravenous administration of novarsenobillon being associated in any way with the development of a positive Wassermann reaction in the blood, in the absence of definite syphilitic infection.

Conclusions.

1. Serological cure, not only in the blood, but also in the cerebro-spinal fluid, can be effected in a sufficiently promising number of cases to warrant energetic use and further improvement of the methods at present utilized in the treatment of neuro-syphilis.

2. It is very desirable, as has been emphasized by numerous workers, that in the routine treatment of syphilis and in the clinical investigation of nervous disease the cerebro-spinal fluid should be examined in every case and its Wassermann reaction tested.

3. There is no evidence of a positive Wassermann reaction being provoked in a non-syphilitic patient as a result of the intravenous administration of novarsenobillon.

To Professor C. H. Browning for the favour of his opinion in the interpretation of many of the Wassermann results, and for much helpful advice, to Dr. Douglas K. Adams for his co-operation throughout the investigation, and to Drs. W. R. Snodgrass and J. McGregor Robertson of the Venereal Diseases Centre for their willing assistance in providing clinical material and in furnishing data concerning their cases, it is a pleasure for the author to have the opportunity of recording his indebtedness.

DISCUSSION.

Dr. ALDREN TURNER (London) said that he would give a summary of the results of treatment of neuro-syphilis by modern methods from a number of cases treated at the National Hospital, Queen Square, London, which had been submitted to analysis by Dr. Macbride and himself. About two hundred cases of different forms of neuro-syphilis had been so treated and the results could be grouped as follows: The first group of about 10 per cent. of all cases, including tabes dorsalis, usually of long standing, in which the clinical picture of the disease was characterized by subjective and objective sensory symptoms, loss of the deep reflexes, ataxia, optic atrophy, etc., but in which the Wassermann reaction of the blood and cerebro-spinal fluid was negative and the cell count was within normal limits. These appeared to be cases in which the activity of the morbid process had abated either spontaneously or in consequence of previous treatment. There was difficulty in determining whether these were cases of arrested tabes, as it was not uncommon to find the occasional recurrence of symptoms, such as pains, crises, or bladder trouble, which were amenable to a further course of treatment. It was not always possible to obtain trustworthy evidence of previous treatment, but the course of the malady and the serological tests favoured the belief that the activity of the disease at all events had subsided.

The second group contained about 75 per cent. of all cases, including general paralysis, tabo-paralysis, and tabes dorsalis, in all of which the symptoms and signs were characteristic, the Wassermann reaction was strongly positive in both serum and fluid, and the lymphocyte count was high. The cases of

general paralysis and of tabo-paralysis in this category were of recent origin and gave a history of progressive development. In the tabetics the duration of the disease was about five years. With the exception of some temporary relief of the subjective sensory symptoms and a reduction in the lymphocyte count, no material improvement resulted from treatment. A few cases appeared to progress in spite of it. The positive quality of the Wassermann reaction in blood and fluid remained unaltered. This formed by far the largest group of paretics and tabetics seen in hospital practice, and their analysis showed that there was much scope for further improvement in means and methods of treatment in a large percentage of such cases.

The third group comprised about 12 per cent. of the cases, including tabes dorsalis of short duration (from two or three months to two or three years) occurring in relatively young persons with typical subjective and objective symptoms, positive Wassermann reactions in serum and fluid, and a high cell count. As a direct and immediate consequence of treatment, the Wassermann reaction became negative or weakly positive, the cell count fell below 10, the subjective sensory symptoms—pains, paraesthesia, etc.—abated, and the general health improved. From the therapeutic standpoint that was an important group, as there was every reason to believe that it might be possible to arrest the progress of some cases of tabes in the early stages by appropriate treatment under certain conditions. As far as could be ascertained at present those conditions are: the commencement of treatment within, if possible, a few months of the onset of the symptoms, persistent treatment over a sufficiently long period, and a repetition of treatment at intervals with periodic serological tests. It was not improbable in those cases that the morbid process primarily attacked the spinal meninges rather than the nervous parenchyma and that by early and vigorous treatment secondary degeneration in the posterior column might be averted.

In the fourth or meningo-vascular group, which included the so-called syphilitic myelitis, meningo-myelitis, and spastic paraplegia, the Wassermann reaction varied considerably, and early treatment might be beneficial. It was, however, important to bear in mind when studying neuro-syphilis and the influence of treatment upon it that the effects of damage already done to the nervous parenchyma remained permanently.

Dr. HENRY J. MACBRIDE (London) said: My contribution to this discussion will consist of observations (1) on changes in Lange's colloidal gold reaction as a result of treatment, and (2) on methods of treatment. The Lange reaction, as we all know, holds a prominent place in the routine examination of the cerebro-spinal fluid, and is a very valuable confirmatory test for syphilis of the nervous system. Lange claimed for his reaction close parallelism with the clinical course of syphilitic disease of the central nervous system, and this claim Vogel and others have supported. Let us consider how far it is justifiable. Before making an analysis of cases we must decide what is a negative and what is a positive reaction. It is agreed by practically every observer that it is quite impossible to obtain for every test colloidal gold solutions presenting the same precipitating power. To add to this difficulty in technique many other pathological conditions may give a curve. Disseminated sclerosis may give even a parietic curve, and from our figures at the National Hospital 9 out of 81 cases gave this type of curve. It is also possible to obtain low curves in fluids from normal people. It is evident, then, that the curve must be marked before it can be considered positive. At the National Hospital a positive curve is one in which there is a discoloration to the extent of "3" in at least two tubes.

Of 100 tabetics whose cerebro-spinal fluid was examined on admission the Lange reaction presented the following results: 35 poor or negative curve; 30 minimal curve; 21 good curve in zone II; 14 parietic curve. Here were 100 cases sufficiently well established to enable the clinical diagnosis to be made and, in fact, for the most part sent into hospital because their symptoms were progressive, yet in 65 Lange's reaction was either negative or indefinite. It can hardly be said, then, that it corresponds with the patient's clinical condition. Furthermore, if the patient's condition improves, no corresponding improvement in the Lange reaction is possible.

I have analysed another series of 35 cases of tabes, tabo-paralysis, general paralysis of the insane, and cerebral syphilis, in which the Lange reaction was observed before and after treatment, and the following are the results. The cases fall

into three groups: (1) those which show a diminution or flattening of the curve; (2) those which show no change in the curve; and (3) those in which the curve became more pronounced.

Group 1.—The cases which showed a diminution of the curve were 14 in number, and of these 13 showed corresponding clinical improvement. Five began with parietic curves which became reduced to low luetic curves. Of these, one was a general paralysis of the insane, treated with intrathecal mercurialized serum on whose cerebro spinal fluid five observations were made. The curve became smaller at each successive examination, although the Wassermann reaction remained strongly positive throughout. Another was a case of tabes treated with mercurialized serum and whose cerebro-spinal fluid was examined eight times. In the second, third, and fourth examinations the curve in zone I was practically negligible; but in the fifth and seventh examinations the curve again became parietic, to disappear once more in the eighth examination. There were no clinical regressions to correspond with the reappearance of the parietic curve. In this case again the Wassermann reaction remained strongly positive throughout. There was one case among the 14 of Group 1 in which the intensity of the reaction diminished and in which no clinical change could be seen.

Group 2.—The cases which showed no change in the curve numbered 15. Six had parietic, or, in other words, maximal curves, which did not alter, and the condition of the patient remained the same or got worse. These were 5 cases of general paralysis of the insane and 1 of tabo-paresis. Nine had negligible curves which showed no alteration after treatment. Clinically these patients showed some improvement. In 3 of these 9 cases the Wassermann reaction was negative in the cerebro-spinal fluid but positive in the blood.

Group 3.—The cases in which the curve became greater after treatment numbered 6. Five of these improved clinically, while one remained clinically unchanged.

Altogether in the three groups 16 cases out of the 35 showed no change in the Lange curve corresponding to the clinical symptoms, and in 6 of these the curve actually increased while there was clinically improvement. From these two series I feel justified in concluding, therefore, that there is no consistent parallelism between the changes in the Lange curve and those in clinical symptoms. The Wassermann reaction, though less sensitive than the Lange, is a more reliable guide to the clinical progress of the disease. At the same time a positive Lange reaction is a valuable confirmatory test, but a negative or indefinite curve has not the same significance. I cannot say how far a positive curve is an indication for further treatment.

Methods of Treatment.

When a patient is admitted to the National Hospital his cerebro-spinal fluid and blood are taken for examination. He then starts on a course of iodide, mercury, and generally intravenous novarsenobenzol. Iodide is started in 10-grain doses and worked up slowly to 25 or 30 grains thrice daily. The mercury is given by inunction, 1 drachm of unguentum hydrarg. daily. With regard to the novarsenobenzol, we begin with very small doses, usually 0.15 gram, and increase through strengths of 0.3 and 0.45 to 0.6 gram, which is the maximum we now give. For occasional cases we give intrathecal injections either of mercurialized serum or of patient's own serum, prepared after two or three doses of novarsenobenzol. With this we combine re-education, massage, rest, and such symptomatic treatment as special cases may require. During the last year over 1,000 injections of novarsenobenzol were given, without precautions in reference to meals and without any accompanying dose of glucose. In no case was there any jaundice. Dermatitis occurred in three cases all at the same time, and was believed to be due to a faulty lot of novarsenobenzol. Sickness was a very rare occurrence. I have said that we generally give novarsenobenzol, but there is one very important exception to this—if there is any sign of optic atrophy. Four cases have come before my notice in which arsenical preparations increased an early optic atrophy. In one of these, a juvenile tabes, the eyesight was fairly good beforehand, but in all probability early optic atrophy was present. Before the patient came under our charge he was treated with an intravenous injection of some arsenical preparation, and the first dose caused complete blindness. It is the opinion of those well qualified to judge that cases of early optic atrophy should be treated very carefully. Arsenic should be avoided if possible and the treatment confined to mercury and iodides.

Dr. A. STANLEY BARNES (Birmingham) remarked that the results of the salvarsan treatment were a little better, but not much better, than those obtained in the old days with mercury alone; in 10 per cent. of all cases the disease tended to die out whether treated or not. The aim should be to find some drug which would percolate more easily. He suggested protein shock in addition to mercury and arsenic injections, in the hope of aiding the percolation of these drugs into the cerebro-spinal fluid.

Sir FREDERICK MOTT doubted if there was much evidence that the arsenical treatment was much better than mercury inunction, and therefore prophylactic treatment—the prevention of the entrance of the organism—was of the greatest importance. In 66 per cent. of fatal cases of general paralysis of the insane organisms could be found in the substance of the brain and in the perivascular spaces; they were found especially easily in four cases treated by intrathecal injection. Mercurial treatment was extremely valuable and inunction the best way of giving it. He referred to the simple and effective Sicard method which gave small doses on alternate days of novarsenobenzol hypodermically or intramuscularly in glucose.

Professor C. H. BROWNING (Glasgow) considered that no satisfactory experimental evidence had yet been offered of the existence of a neurotropic variety of spirochaete. The problem of therapy in nervous disease was very difficult; all cases attending a venereal clinic should be examined as to their nervous system to determine at what stage neuro-syphilis arises.

Dr. DAVID LEES (Edinburgh) spoke from an experience of 3,000 to 4,000 cases of early syphilis in which he had tried all methods of treatment previously mentioned except that by intracranial injection. He was not satisfied that any better results were obtained by spinal drainage than by the Sicard method, but in eight of nine cases of tabes in which Quéry's monkey serum was used intramuscularly very definite improvement followed.

The PRESIDENT (Professor G. M. Robertson, Edinburgh) outlined the development of our knowledge of general paralysis of the insane, and moved the following resolution: "The members of the Section of Neurology and Psychological Medicine of the British Medical Association send their congratulations to the Dean of the Faculty of Medicine of Paris on the occasion of the centenary of the presentation of the thesis by Bayle entitled *Recherches sur les maladies mentales*, in which for the first time the view was expressed that the symptoms of paralysis complicating insanity were those of a distinct disease now known as general paralysis of the insane. The discovery and differentiation of the symptoms of this disease are justly regarded as one of the greatest advances ever made in neurological and psychological medicine and the whole credit of this is due to the observations of Parisian physicians, especially of Esquirol, Rogor-Callard, and Calmeil. The members of the Section further desire to express their sense of the great debt they owe to French neurologists and psychiatrists for this and for much other work in their special branch of medicine." The resolution was seconded by Sir Frederick Mott and carried with acclamation.

ON THE ELEMENT OF CONTRAST IN THE PSYCHIC MECHANISM.

BY

J. H. MACDONALD, M.B., F.R.F.P.S.G.,

Mackintosh Lecturer in Psychological Medicine, Glasgow University.

Psychologists are agreed that the whole mental structure of evolved man rests upon the laws of association of ideas. It has been shown that the great bulk of associations common to all men are capable of being included within two main categories—namely, those founded upon resemblances and those upon contiguity in time and in space.

Some authors have written of these two categories as intrinsic and extrinsic, and others again as internal and external. Various subtypes of associative bonds have been recognized, and amongst these there are some that are individual rather than general—for example, associations between a word and a letter (clang associations), between a letter and the name of a colour, between a number and a colour, etc. No doubt the prevailing type in any particular individual is due in great part to training, education, and

habit—for example, the reasoner as against the descriptive writer; but it also depends upon innate factors—that is to say, factors intrinsic in the developmental potentialities of the neural mechanism. A congenitally blind man cannot associate yellow colour with the word "orange"; the artist and musician perceive shades of colour and qualities of tone and harmony that lie without the perception of others. In this way we have come to recognize differences in the mental make-up of separate individuals, these differences depending upon the prevalence of particular types of associative links in the ideative mechanism. It has been pointed out, for example, that the majority of men are auditory rather than visual, but a considerable number show a prevalence of visual images and associations, whilst others again are decidedly tactomotor.

Amongst the special varieties of associative bonds that can be distinguished there is, however, one which is common to all men, and at the same time so powerful in many that it deserves to be considered in a category by itself. I refer to associations due to contrast.

From the dawn of consciousness in the human infant, from the moment there begins to arise a distinction between the external and the internal, between that which is self and that which is not self, there begins a struggle which is characterized by a contention of elements for and against existence and expansion. In this contention contrasting elements are ever in evidence, and, as experienced augments, the opportunities of contrast become ever more subtle and complex. "Man," wrote Dumas, "is a strange animal wholly made up of contrasts." That statement may not carry conviction on the face of it, but a little consideration of the subject will soon convince one that it is in great measure true.

It is noteworthy that, centuries ago, philosophers and psychologists recognized the fact that contrast played an important part in the ideative processes. "When we seek," said Aristotle, "after an idea which is not immediately before us, we reach it through the mediation of another idea, either by resemblance or contrast or contiguity." Yet I have found on consulting a number of modern textbooks of psychology that comparatively little attention is devoted to contrast as an element of any particular importance in the psychic mechanism. Some authors omit this subject entirely, whilst others make only a passing reference to it.

Professor Baldwin, in treating of the laws of association of ideas, admits that at first sight one might be warranted in citing contrast as a distinct principle of association. "If the sight of a dwarf brings up a giant, if sour makes one think of sweet, there can be no doubt," he says, "in such cases of contrast of the reality of the association; but," he asks, "are there not other reasons than that of contrast to which it may be referred?" He answers: "There are such reasons; it seems, in all cases, and we are led to reduce these associations to resemblance and ultimately to contiguity. In most cases of contrast," he argues, "there is a standard of reference to which both the presentation and the revived image are referred; this standard constitutes a point common to both ideas, a point of resemblance. For example, the short man suggests the tall, since both are, at once, thought of in comparison with an average man. The one is short only as he is shorter than usual, and the other is tall only as he is taller than usual. Thus in the very conception of the contrasted images a common element enters. This common element . . . secures the association by contiguity."

The view thus expressed by Baldwin would appear to have been endorsed by many other writers; but, however logical it may appear to be, it does not really invalidate the position of those who would regard contrast as in itself a distinct and fundamental principle of association. It merely brings into prominence the fact that we can distinguish degrees of contrast and, further, that contrasting ideas are brought into contiguity in consciousness by the very reason of their contrasting character. After all, contiguity itself can only be conceived in relation with the conception of separation or remoteness.

The general law would appear to be that the first and last components of a series are more closely associated than the intermediates; in other words, that associations are more prone to be formed between maximal than between minimal contrasts. In the field of the sensations, for example, black is more closely associated with white than with the intermediate shades of grey. Heavy is associated with light, smooth with rough, and so on. In the field of the emotions we have pleasure associated with pain, friendship with enmity, love with hate, whilst in the higher field of the sentiments

we have the moral associated with the immoral, cowardice with courage, etc.

It would seem to be the case that it is where thought embraces factors that are attributive—that is to say, qualitative, quantitative, or distinctly affective—that the element of contrast is particularly apt to come into play. Where the more or less purely cognitive factors in thought predominate in consciousness, there is less likelihood of contrasting elements becoming prominent. "Sweet" finds ready association with "sour," "long" with "short," "good" with "evil"; but "horse" is not unlikely to be associated with "stable" or "cart" or "race," "desk" with "office" or "papers," "pen" with "ink," and so on. In the latter examples the affective element is weak and contrast unlikely. So, too, in many ideative processes, such as are involved in the pursuit of scientific problems and reasoning to a logical conclusion, the ideative process may be sustained with a predominance of cognitive factors and a relative absence of contrasting elements. Even under such conditions, however, conditions involving processes of cold calculation or abstract reasoning, difficulties may arise. The happy solution of the problem or the attainment of the end in view may, after long and sustained thought, appear no nearer; unforeseen obstacles may arise, steps may have to be retraced, failure may threaten and, with that, discouragement may supervene, bringing in its train numerous contrasting ideas. Apart from that, however, the fact remains that a great part of the everyday mental activity of the generality of men, that part concerned in the things that matter in the struggle for existence, in the attaining of success, the getting of comfort, in short, in the expansion and development of the individual and social ego, is characterized by strong affective tones of consciousness, which permit the play of contrasting ideas for and against.

Here I would like to dwell for a moment on the part played by the affective or emotional element in thought as an important associative link in the ideative processes, for I am inclined to think that it deserves more attention than has been accorded to it by the majority of writers. I will not attempt to enter into any discussion as to the nature and genesis of emotion—that lies entirely without the immediate scope of this paper. I will simply remind you of the biological law that every stimulus which acts upon a living organism is harmful or beneficial, integrative or disintegrative in its effect upon the organism.

(It may be argued that some stimuli are indifferent in their effects, and in this connexion allusion may be made to modes of natural energy which are constantly impinging upon our bodies, which yet awaken no sensation whatsoever—for example, emanations of radium and the ethereal vibrations of the ultra-violet rays which do not reveal themselves to our unaided senses. Were we to pursue this argument we should have to discuss the distinction between mere reception of energy and sensation and all that is involved in the old problem, "Where does sensation begin?" The study of all that is comprised within the term "kinaesthesia" goes to prove that the biological law referred to is fundamental and permits of no exception; that, indeed, every stimulus which penetrates the organism has an integrative or disintegrative effect, no matter whether it does or does not awaken sensation. One might refer in passing to the varying response of the muscles of the iris to different intensities of light, the unaccompanied by sensation yet certainly protective and integrative in its effect.)

Leaving aside the disputed question of indifferent stimuli, one can certainly say that whenever a stimulus penetrates the organism and arouses sensation that sensation has qualities or attributes which can be spoken of as beneficial or harmful, integrative or disintegrative. Similarly all our percepts, which at bottom are complexes of sensations, have their sensational accompaniments which give rise to tones or modes of consciousness to which we ascribe the so-called emotional attribute of pleasure or of pain. When we rise from perception to ideation analysis convinces us that every idea bears with it a mnemonic residuum of the particular sensational and emotional attributes that belong to its perceptive content. This emotional concomitant which attaches to every idea frequently serves as a powerful bond of association in the ideative processes. In illustration one might cite the case of a man to whom an unexpected fortune has come. We say he is overflowing with happiness. His consciousness is occupied with ideas which have as their affective components the emotional element of joy. It is not likely that painful ideas will spontaneously arrest his attention. If

cannot be at once gay and sad. The prevailing bonds of ideative association in this case lie more in the affective than in the cognitive elements. No doubt the usual associative links of similarity and contiguity are each in evidence, but the first importance attaches to the affective elements. The condition is well exemplified in the expansive maniac whose incoherent flight of ideas often lacks any consistent associative bond other than the emotional.

Professor James² is found amongst those who emphasize the important part played by the emotional bond in the associative processes. He speaks of it as "emotional congruity" and places it along with habit, recency, and vividness, as affording an explanation why one rather than another of many possible associations should follow a particular stimulus. In this connexion Professor James speaks more particularly of normal mental action, but it is a fact that the influence of emotional congruity upon the mental mechanism is even more striking in cases of mental disorder.

Emotional congruity is but another term for emotional similarity or harmony, and thus it may be brought within the category of the associative bonds founded upon resemblance. At the same time it is worthy of notice that the factor of contrast may come into play here also. It is widely recognized that the same images and objects do not constantly bring into consciousness the same associates. As James has well said, "The records of Arctic or African travels, perused in one mood, awaken no thoughts but those of horror at the malignity of nature; read at another time they suggest only enthusiastic reflections on the indomitable power and pluck of man." Speaking from his own experience he declares that "few novels so overflow with joyous animal spirits as *The Three Guardsmen* of Dumas. Yet it may awaken in the mind of a reader depressed with sea-sickness, a most woful consciousness of the cruelty and carnage of which heroes like Athos, Portos, and Aramis make themselves guilty."

Similar experiences are doubtless common to all of us, but the contrasted states of consciousness which arise as a result of the same images probably find their explanation in an altered kinaesthetic tone of consciousness. The pleasures of yesterday lie as a pall upon us to-day. At first thoughts one might conclude from such instances that the same ideas have not always the same emotional concomitants inherent in them, but that would be a very wrong conclusion. If at one period of our lives the exploits of the Three Musketeers excite within us enjoyable emotional states and at a subsequent period awaken opposite feelings of repugnance and horror, the emotional contrast finds its true explanation in the fact that on the second perusal a new order of ideas has arisen, these ideas bringing along with them their own peculiar emotional tone. In the example just quoted the repugnance experienced on the second perusal is the natural consequence of ideas of bold bad men who delight in bloodshed and deeds of evil daring. These ideas differ from those that were present in consciousness on the previous occasion.

Expressed in another form, it can truly be said that the same images and objects are not always succeeded in consciousness by the same associates, but that is a very different thing from saying that the same ideas have not always the same emotional concomitants. Again, our ideas of particular objects may alter from time to time as our perceptions of these same objects and their relations become more perfect and complete, so that along with cognitive development there will be emotional variation, always, however, in strict relation with the cognitive variation.

I wish to lay particular emphasis upon the latter point, because not a few authors who have discussed psychological problems in recent times from a psycho-analytical point of view have proffered as explanations of certain morbid states the splitting off of the affective element from a certain order of ideas to which it properly belongs and its transference and attachment to another order of ideas, often of a contrasting nature. Such an explanation (like some other propositions, advanced by certain psychoanalysts) may be plausible, but it does not withstand criticism, nor does it accord with well-established biological principles founded upon the study of the evolution of psychic phenomena.

To my mind the cognitive and affective elements which together compose any particular idea are as inseparable as the heat and the light which we find associated in the glow of an incandescent lamp, which together, and only together, give the incandescence. It is true that the heat and the light may vary with variations in the quantity of energy which is expended, and, again, that the same amount of energy can be made to give variations in heat and light if the disposition of

the apparatus is altered and new elements are interposed in the circuit. Similarly, the intensity of the affective and cognitive elements of an idea may vary in consciousness from time to time according to the intensity of the stimulus that has re-evoked it, and according as new elements intervene in the nervous mechanism involved.

What is true of one idea is equally true of trains of thought. The intervention of new elements coincides with perceptive and ideative developments, and with the kinaesthetic variations which underlie and afford the explanation of our variable moods and temperaments. All emotional states are bleached with the kinaesthetic waves which arrive at the central nervous system from every organ and tissue, though these do not in normal conditions awaken consciousness.

Contrast provides us with a useful biological distinction between lower and higher forms of consciousness. Professor Bianchi³ of Naples, in treating of the phenomenon of consciousness, alludes to the difficulty which all psychologists and philosophers have experienced in attempting to define the point in the scale of living organisms where consciousness can be said to be first manifested. He provides, however, a very useful and suggestive contribution to this discussion in his distinction between what he calls lower consciousness and higher consciousness. Higher consciousness, according to Bianchi, is an attribute of all evolved human beings, and it may possibly be ascribed to the higher mammals, which, to the external observer, seem to give evidence of reasoning capacity. The dawn of higher consciousness would coincide with the appearance of contrast between actual images and those furnished by memory of past experience.

"If I prevent my dog," says Bianchi, "from making off with a piece of meat and then go away with forbidding and threatening air, leaving it beside the dog, he refrains from touching it. Such behaviour represents an impulsion resulting from the internal struggle between hunger, desire, the impulsion to eat the piece of meat, and the prohibition received. It is conscious behaviour. If desire and hunger gain the upper hand and the dog seizes and eats the piece of meat and, then, very repentant and fearful, hides himself or runs a long way off, only to return home after a time full of compunction and humiliation, imagining that he will have to confront his master's displeasure, this is consciousness made up of memories, associations, imagination, and sentiment." It is conscious rather than instinctive behaviour, inasmuch as it involves the recall of past percepts and the contrasting of these in consciousness with the percepts of the moment. We can recognize in such behaviour a play of memory, and a choice from amongst contrasting images—factors which form the basis of discrimination, reasoning, and judgement. It is considerations such as these that induce Bianchi to advance the hypothesis that " whilst consciousness has its nucleus in sensations and organic movements, and doubtless may be fashioned in different manner in different beings, yet evolved consciousness, quiescent from the *rencontre* of the actual perception or representation with other confirmatory or contrasting percepts furnished by the memory of previous states of consciousness conserved in the unconscious."

The more closely conduct approaches to behaviour which is an immediate outcome of percepts or representations of the moment, the more it presents the character of immediate reaction to a particular stimulus, the more invariable and uniform the memory involved, or, expressed in other terms the more it is the resultant of the flow of nervous energy along habitual and unvarying nervous pathways, the more does it sink to the level of the instinctive. Intelligent behaviour on higher levels results from the intervention of more numerous representations furnished by a memory which is multiform and variable, varying as it does with length and breadth of experience, a memory which permits the play of ideas for and against, with the ultimate ascendancy of some over others, manifested in conduct which represents a more perfect adaptation to circumstances. Here one can conceive the underlying mechanism to involve a flow of energy along more numerous and complex nervous pathways, some convergent in one direction, others divergent or convergent towards an opposite direction, the issue being dependent upon the ultimate sarcharge of one rather than another of the different sets of neuron routes involved. In brief, there is herein brought into play all that extensive mechanism which we conceive to underlie all that is included within the terms memory, reflection, discrimination, choice, judgement, reasoning, inhibition, and will.

It is clear that the greater the store of utilizable mental

capital, or, in other words, the more extensive the memory and the more facile the process of recall, the greater will be the opportunity for contrasting elements to come into play, the greater will be the range of adaptability of the individual to his environment, and the greater the probability of success.

There are exceptions to every rule. Instances will occur to your memory of men who have on occasions achieved success without much reflection, where others with greater powers of discrimination, of contrasting the pros and cons have failed. The rash speculator who makes a successful plunge into the stock market will afford a ready example. We commonly declare his success to be due more to good luck than can be good judgement, and it is not from such examples that we seek to deduce laws that may usefully regulate the conduct of men in general. If, as not infrequently happens, a great store of knowledge does not coincide with highly intelligent conduct, that is probably to be ascribed to a relative paucity of contrasting ideas or a lack of facility in recalling contrasting ideas from the mnemonic capital, always taking into account the influence of habit.

I have already made passing reference to the differences that can be distinguished in different individuals in the formation and expression of ideas according as there is a predominance of auditory, visual, and tactomotor elements in their mental make up. Differences may likewise be founded upon the relative absence or frequency of contrasting elements. Such differences will depend partly upon qualities intrinsic in the nervous substance, but they are partly to be explained by the law of habit, which here, as in most aspects of the mental mechanism, is of great importance. This fact finds tacit recognition in the upbringing of the infant and the education of the child.

It is probably the case that the dawning consciousness of the infant rests upon vague and confused contrasts between inner and outer relations, between the self and the non-self, between sensations of comfort and discomfort. The child is taught to recognize and distinguish between different objects by having pointed out to it that the one possesses features or qualities which are absent in another and vice versa. Thus occasions permitting contrast are constantly arising. From an early age the child is ever being impressed by parents or instructors to "do" this and "don't do" that, that this is "good" and that is "bad." These injunctions, drawn as they are from the maturer experience of elders, are often beyond the child's philosophy. That they are often in contrast with its natural tendencies is evidenced by the mode in which it receives them, its wonder, and its "whys" and "why not's." Just here lies the great distinction that separates the human being from brute creation.

In his discourse upon reasoning, Professor James has declared that the "characters whose presence impress brutes are very few, being only those which are directly connected with their most instinctive interests. . . . A thing may remind a brute of its similars but not of things to which it is but slightly similar; if the most prosaic of human beings could be transported into his dog's soul, he would be appalled at the utter absence of fancy which there reigns. Thoughts would not be found to call up their similars but only their habitual successors. Sunsets would not suggest heroes' deaths, but supper time. That is why man is the only metaphysical animal. To wonder why the universe should be as it is presupposes the notion of its being different, and a brute who never reduces the actual to fluidity by breaking up its literal sequences in his imagination can never form such a notion. He takes the world simply for granted and never wonders at it at all."

Again, it may be pointed out that a great part of education in early years is based upon the principle of impressing definite ideas upon the child and of encouraging certain habits of thought and conduct rather than others. Such forcible impressions necessarily imply repressions towards thought and action in other directions, although the contrast involved may not be brought prominently before the child's consciousness. Taken as a whole, the pedagogic method or system is logical and good, and is perhaps the only method available as a short cut to the acquisition of the knowledge laboriously acquired by preceding generations. There is a point here, however, which should have great significance to the compilers of scholastic schemes. The forcible application of methods and systems designed for the mass, but not necessarily appropriate to the individual, contains a certain element of danger.

After the child has suffered repressions and inhibitions in

the domestic circle, under parental or other authority, he proceeds to the elementary school, where he is submitted to a process of training which is based largely upon the idea of encouraging certain habits of thought and conduct and discouraging others. It very often happens that by the time he has reached the age of 11 or 12 he has lost a great deal of the curiosity and inquisitiveness that characterized his earlier years. He has learned to appreciate the fact that things are not always what they seem to his untutored mind, and at the same time has acquired the habit of accepting from his parents and instructors the explanations which they proffer of the many problems that may come before him, without much discussion. If the father or mother or teacher says so then it is right. He has acquired habits of credulity and obedience, but this unfortunately is at the expense of criticism and discrimination. Contrasting notions, upon which discrimination is largely based, are not encouraged.

All this is no doubt mainly to the good, considering it is true that the system of education that is involved has been compiled, generally speaking, from experience gained by older and wiser individuals. It represents a method of imparting knowledge that is most promising of useful results, but it makes no allowance for individual variations in natural tendencies. Generally speaking, early home and school training does not encourage the habit of criticizing, which largely depends upon ability to bring contrasting notions together in consciousness. Notions, doctrines, and explanations laid down with authority by parents, teachers, or elders are apt to be accepted without much questioning by children. Habits of thought thus early impressed are not readily broken. (Many of us have doubtless had experience of this in the religious teaching which was imposed upon us in our earlier years, about the accuracy or tenability of which we may have come to have some doubts only after the lapse of many years.) Comparatively few are by nature, or rather should I say, by habit and education, intensely critical and penetrating, and many of us experience a kind of shock when beliefs we have cherished are assailed and shown to be untenable.

Apart from matters of faith, our beliefs in matters of fact are greatly influenced by early training, and misconception of later years no doubt finds its explanation in the difficulty that is experienced in overcoming the resistances which contrasting ideas imply. "Get hold of the children," say those who are interested in the implantation and spread of new principles or doctrines; but whilst we recognize the good that is in the system, we must not shut our eyes to the evil. Socialistic, ascetic, and revolutionary doctrines preached constantly with the voice of authority by parents or teachers or elders are certain in a large number of instances to be accepted without much criticism because they have the stamp of authority upon them. Whether they will afterwards be rejected or modified will depend to a large extent upon subsequent environment and experience—that is to say, upon the opportunities occurring in the life of the individual for the play of counter-influences and the formation of contrasting notions.

What I have hitherto said has had reference more particularly to the part played by the element of contrast in the normal mental mechanism, but a little reflection will show that the subject is worthy of further study in relation to many morbid mental phenomena. Speaking generally, one might say that many mental disturbances are associated with deficiency in number or potency of contrasting ideative elements, whilst others show a morbid preponderance of contrasting notions over those other ideas which have been the means of their recall into consciousness.

The contrasting capacity is very limited or absent in idiots, imbeciles, and mental defectives, whose mental life revolves in narrow spheres, characterized by simplicity as well as paucity of ideas. Their defective judgement and discrimination may be explained as largely dependent upon their inability to compare and to contrast. At the other end of the scale demented find themselves very much in the same position either because of their loss of mental capital or their inability to recall from their mnemonic store the requisite confirmatory and contrasting elements which form the basis of sound judgement.

Again, the impulsivity which is so prominent a feature of the epileptic psychosis, as well as of mental deficiency and certain forms of mental enfeeblement, may be interpreted as affording evidence of the lack of contrasting notions. If an idea, having presented itself in consciousness, is immediately translated into action in the rash and precipitate manner so

characteristic of the epileptic, that would signify not only great accessibility and permeability of the motor paths, but also a failure to call forth contrasting ideas with their inhibitory accompaniments. There is here a sort of short-circuiting as compared with what we conceive to occur in processes involving contrast, choice, and volition.

So, too, in many dreams the rapidity and amazing ease with which we fancy notions to be realized under conditions which to our waking consciousness seem incongruous and illogical, may be conceived to be due to a similar short-circuiting, or, in other words, to the non-intervention of all the normal associative mechanism with its representation of confirmatory and contrasting notions and tendencies, which is the feature of the fully conscious state.

Whether we do or do not accept the prevalent notions of the subconscious and the unconscious as set forth by the exponents of the modern psycho-analytic doctrines, we are compelled by the facts of experience to admit different intensities of consciousness even in the waking state. There are times when the thinking process is intensely active, when representations are clear and recall their various confirmatory and contrasting associates with readiness and facility, when ideation is sustained and logical conclusions are arrived at. At other times (associated, it may be, with fatigue or toxæmia) we experience great difficulty in pursuing trains of thought, memory is unfaithful, and even with effort we cannot think clearly, notwithstanding the fact that we are quite awake and conscious.

Again, practically all human beings are more or less given to abstraction. Abstraction, when it takes place with full consciousness, pursuing preconceived ends, furnishes us with examples of inventive imagination. In states of less intense consciousness it gives us reverie and day-dreaming. When we allow our thoughts to wander, as we say, the new formations that arise from unwonted ideative associations are often absurd and illogical. When we regain our normal state of consciousness we recognize them to be fantastical and out of harmony with reality, which furnishes a number of contrasting images. These new formations do not fit in with our preformed notions. They do not become attached to the latter with strong associative bonds and so are readily forgotten, at least in normal man. Yet it should ever be borne in mind that they represent actual psychic new-formations which under appropriate circumstances may be recalled or re-enacted. The requisite conditions may be found in states of low intensity of consciousness—as, for example, in subsequent periods of reverie or in dreams or in conditions of delirium, when something akin to short-circuiting in the psychic mechanism again becomes the rule.

Many automatisms furnish us with examples of mental action which is characterized by absence of psychic contrast. An extreme example is afforded by the somnambulist, who unhesitatingly pursues his course in dangerous positions, quite oblivious of the risk he runs; the feats he unconsciously performs would be beyond his achievement in the waking state, when the situation in which he would find himself would evoke contrasting ideas of risk and danger, along with their inhibiting concomitants. Something akin to this takes place in normal men who perform certain actions which they would not dream of performing with a fuller knowledge of the circumstances involved. The condition has been summed up in such sayings as "Where ignorance is bliss 'tis folly to be wise," and "Fools rush in where angels fear to tread."

The so-called functional psychoses, hysteria and psychasthenia, including the obsessions and phobias, offer us a most extensive field for the study of the mechanism of psychic contrasts and the influence of these upon conduct and adaptation. Hysterical subjects are notoriously unstable, and they present the strangest contrasts and paradoxes in thought and action. These are frequently nothing more than the external manifestations of contrasting ideative processes, ranging from simple to the most complex. A simple example is afforded by the tendency of the hysterical subject to act contrary to a given injunction. One meets with this condition episodically in people who are not commonly regarded as hysterical. The notion of refraining from coughing or yawning may bring with it the contrary desire to cough or yawn, which often proves irresistible. In this respect hysterical people present features of infantilism reminding us of the common tendency in infancy to act contrary to a given injunction.

Hysterical and neurasthenical subjects who display great devotion to a particular cause are often driven thereto by contrary notions and emotions. Intense egoism and vanity

are sometimes translated into acts of altruism and charity. Some who have long dedicated themselves to religious duties and practices subsequently become mastered by erotic and lascivious notions utterly in contrast with their vows. The truth would seem to be that the antithetic notions and tendencies have never been entirely wanting, though they have not occupied consciousness to the same extent, and that after years of inhibitions and repressions on one hand and exaltations on the other there ensues a period of nervous exhaustion (to which various factors may contribute) which disturbs the inhibitory balance in favour of those elements the activity of which has hitherto been kept in check, so that the latter are now allowed free course. The eroticism and immorality displayed at the climacteric period by some individuals, men and women, who have not hitherto been regarded as hysterical, whose conduct, however, at this time makes strange contrast with their previous behaviour, is doubtless to be explained on similar lines.

In many phobias and impulsions we have examples of the coercive power which contrasting notions may exert. The thought of doing some action or the desire to avoid some deed which is out of harmony with the proper personality brings into consciousness a number of notions correlated with the action in question. The sufferer is in most instances painfully conscious of the irrational character of the contention which ensues between the ideas alternating in his consciousness, but despite his efforts his conduct is dominated by the irrational contrasting notions and emotions.

The neurasthenic who trembles at the notion of suicide may one day be impelled to an act of self-destruction. Apart from actual neurasthenia, recognized as such, we sometimes hear of sudden suicide in the case of individuals who have not previously given evidence of disturbed mental balance and where inquiry fails to reveal any assignable motive for the act. It may be suggested in such cases that the idea surprises consciousness in a weak moment when the regulative powers are low. The antithetic notion which should normally come into consciousness, supported by a train of associated ideas, the excito-motor resultant of which tends to action in an opposite direction, fails to be evoked. It remains inactive or feebly active in the unconscious and the morbid idea of suicide finds its motor path unobstructed. There is no contest for or against. There is no inhibition. The end is inevitable. The thought is translated into the deed. Possibly the same reasoning is applicable to linguistic ties—in the form of coprolalia exhibited by many insane persons, who, when they had control of their faculties, were never known to utter obscene language.

Many delusions of the insane may find their only explanation in the coercive domination of ideas which are brought into consciousness by the mechanism of contrast. I cite the case of a woman brought to the asylum because of delusions of grandeur which led her to lay claim to the possession of a valuable estate in England, bequeathed to her, she imagined, by a noble lord. Inquiry showed that she was indeed in very humble circumstances, but a very devoted mother to two young children. Deserted suddenly by her husband and confronted with poverty, which destroyed her plans and paralysed her actions for her children's future welfare, the contrasting notion of wealth and of the benefits it confers took possession of her consciousness and became the nucleus of an organized system of delusions.

It is not my purpose here to discuss the various other elements concerned in the genesis of delusions. It is sufficient at the moment to say that investigation will show that in very many instances, more particularly in the case of primary delusions—that is, those which are not immediately dependent upon hallucinatory disturbances—the delusional ideas have been brought prominently into consciousness, in the first instance, by the mechanism of psychic contrast.

There is one other point to which I wish in conclusion to make brief allusion. Contrast, as we have seen, is a fundamental and important element in the psychic mechanism, inseparable from the acquisition of knowledge of the outer world; but knowledge of the outer world implies the reception of energy from the external universe. The contrasts which are revealed to us in the intimate natures of objects and relations become facts of consciousness, but it is true that all psychic products resulting from the transformation within the nervous system of the various forms of cosmic energy tend ultimately to find expression in movement, in the form of speech and action. In this transformation and extrinsication of energy we recognize all that is included in the terms "behaviour" and "adaptation."

Within the limits of normal psychic functioning we are frequently conscious of the play of contrasting notions and emotions with correlative intuitions or impulses to movement on the one hand and inhibitions and repressions on the other.

Whether it be in the form of deliberation and reasoning to a conclusion without immediate action of a gross kind, or the weighing of the pros and cons with determination to immediate action, the conflict between the opposing tendencies, intense though it may be, does not greatly disturb the personality, provided there is a definite issue and harmonious adaptation. Where, on the contrary, there is vacillation and indeterminateness consequent upon the monopolization of consciousness by contending notions and emotions, conflict becomes distinctly morbid, because on the one hand it restricts psychic action within unduly narrow limits, preventing the utilization of a great part of the mental capital, and on the other hand it interferes with the reception and assimilation of stimuli from without which are the constant accompaniments of normal relations with the environment.

It is clear that the psychology of conflict which has occupied such a prominent place in recent literature cannot be adequately and rationally discussed without a full appreciation of the part played by contrast in the normal psychic mechanism, more particularly in relation to all the processes involved in ideation and emotion, attention, discrimination, judgement, choice, volition, and inhibition.

EPILEPSY AND GUNSHOT WOUNDS OF THE HEAD.

[Abstract.]

Dr. W. ALDREN TURNER (London) said that out of 18,000 cases of gunshot wounds of the head under the Ministry of Pensions 800, or less than 5 per cent., have developed epilepsy. It is met with in two classes of case: (1) following slight trauma without obvious injury to the skull or brain; (2) true traumatic epilepsy, following injury to the skull or brain, and associated usually with paralytic symptoms. In the first class it is often difficult to say how far the fit may be attributable to the head injury, but it is an important point on account of the number of ex-service men who have received a minor gunshot wound of the head and who state they have in consequence become epileptic.

In true traumatic epilepsy the disability is characterized by seizures having the characters of ordinary epilepsy which may follow injury of any part of the brain except the cerebellum, independent of the extent or severity of the lesion. The time of onset of fits after injury varies from six months to two or three years. Jacksonian epilepsy is rare in comparison with the incidence of ordinary traumatic epilepsy.

Traumatic epilepsy following wounds of the brain is attributable in part to the injury, but in greater part to the constitutional disposition of the patient; local conditions at the seat of injury only in part explain the phenomena. The very small percentage of cases of gunshot wound of the head which develop epilepsy is remarkable, especially when it is known that "anchoring" of the brain to the scalp and the extensive destruction of the skull associated with paralytic symptoms are, in the majority of cases, not associated with epilepsy.

THE Medical Officer of Health for Cairo City in his recently issued report for 1920 states that during that year 40,054 vaccinations were carried out by the medical officers of the inspectorate and districts. Of these 30,623 were primary vaccinations, principally of native children. The corresponding figures were 27,292 in 1919, and 25,613 in 1918. The number of cases of small-pox notified during 1920 was 157, as compared with 1,455 in the previous year.

THE second international congress of military medicine and pharmacy will be held in Rome next spring, beginning on May 28th. The first congress was held in Brussels in July, 1921. The chief subjects for discussion at Rome will be the general principles of the evacuation of the sick and wounded, the co-operation of civil and military authorities in the prevention of disease, chemical laboratories in the field, and the treatment of penetrating wounds of the chest. The subscription is fr. 25. Further particulars can be obtained from the Director of the *Giornale di Medicina Militare* at the Palazzo del Ministero della Guerra, Roma.

THE SURGICAL TREATMENT OF GASTRO-JEJUNAL AND JEJUNAL ULCERATION.*

BY

GARNETT WRIGHT, M.B., F.R.C.S.,

HONORARY SURGEON, SALFORD ROYAL HOSPITAL.

I HAVE elected to bring before your notice to-night a record of surgical failures, believing that one way to progress lies in the study and analysis of our unsuccessful cases.
